SECTION I - GENERAL INFORMATION

| | | |
|--|--|------------------------------------|
| Characterization Aldehyde | RCRA Number None | EPA Class Not Applicable |
| DOT Proper Shipping Name Isobutyraldehyde | Chemical Abstract Service (CAS) Number 78-84-2 | |
| DOT Hazard Class and Label Requirements Flammable Liquid | DOT Emergency Guide Code 26 | |
| DOT Identification Number UN 2045 | Chemical Formula C₃H₇CHO | |

Synonyms

2-Methylpropanol; 2-methyl-1-propanol; isobutylaldehyde; 2-methylpropionaldehyde; isobutyric aldehyde; isobutyl aldehyde; isobutyric aldehyde; valine aldehyde.

SECTION II - HAZARDOUS INGREDIENTS AND IDENTITY INFORMATION

| Hazardous Components (specific identity) | OSHA Exposure Criteria | NIOSH Exposure Criteria | Immediately Dangerous to Life and Health (IDLH) | ACGIH Exposure Criteria |
|--|---|---|---|---|
| Isobutyraldehyde (derivation: By the oxo process reaction of propylene with carbon monoxide and hydrogen; dehydration of isobutanol). | PEL: Not Established STEL: Not Established | REL: Not Established STEL: Not Established | Not Determined | TLV: Not Established STEL: Not Established |

SECTION III - PHYSICAL AND CHEMICAL CHARACTERISTICS

| | |
|---|---|
| Boiling Point 147°F (64°C) | Specific Gravity (H ₂ O = 1) 0.783 |
| Vapor Pressure (mm Hg) 6 at 69°F (20°C) | Molecular Weight 72.1 |
| Vapor Density (Air = 1) 2.5 | Melting Point -87°F (-66°C) |

Solubility

Slightly soluble in water; soluble in alcohol, acetone, benzene, carbon disulfide, chloroform, and ether.

Appearance and Odor

Clear colorless mobile liquid with a pungent odor.

SECTION IV - FIRE AND EXPLOSION HAZARD DATA

| | |
|--|--|
| Flash Point (method used) -20°F (7°C) opened cup | Explosive Limits in Air % by Volume LEL: Not Determined UEL: Not Determined |
| NFPA Classification Class IB Flammable Liquid | Autoignition Temperature Not Determined |

Extinguishing Media

Use water spray, dry chemical, alcohol foam, or carbon dioxide. Use water spray to disperse vapors.

Special Fire Fighting Procedures

Poisonous gases are produced in fire. Wear full protective clothing and self-contained breathing apparatus (SCBA). Heat will build pressure and may rupture closed storage containers. Continue to cool containers with water spray after fire is extinguished. Water on fire itself may be ineffective.

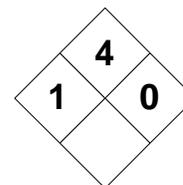

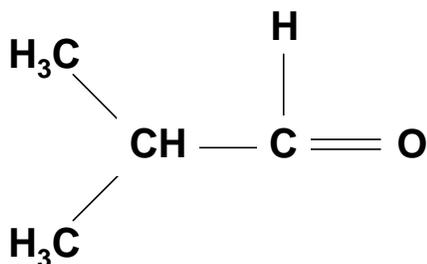

Unusual Fire and Explosion Hazards

Immediately withdraw if rising sound from venting device is heard or if fire is causing discoloration to the tank. Vapors may travel to a source of ignition and flash back.

| SECTION V - REACTIVITY DATA | | | | |
|---|----------------|---|--------------------|---|
| Stability | | Conditions to Avoid Isobutyraldehyde is normally stable under routine conditions of storage and handling. Avoid contact with heat, flame, or other sources of ignition. In contact with air, it will slowly oxidize to isobutyric acid. | | |
| Stable X | Unstable | Incompatibility (<i>materials to avoid</i>) Reacts violently in contact with strong oxidizers (perchlorates, peroxides, permanganates, chlorates, and nitrates). Do not allow isobutyraldehyde to remain in contact with air for prolonged periods. | | |
| Hazardous Polymerization | | Conditions to Avoid Under normal conditions of temperature and pressure, isobutyraldehyde is not known to undergo hazardous polymerization. | | |
| May Occur X | Will Not Occur | Hazardous Decomposition or By-products When heated to decomposition, isobutyraldehyde emits acrid and irritating smoke and fumes, including carbon monoxide. | | |
| SECTION VI - HEALTH HAZARD DATA | | | | |
| Primary Route(s) of Entry: | | Inhalation? X | Absorption (skin)? | Ingestion? X |
| Health Hazards INHALATION: Vapors can irritate the nose, throat, and lungs. High exposures may cause a buildup of fluid in the lungs (pulmonary edema), a medical emergency. May also cause symptoms of dizziness and lightheadedness. SKIN & EYES: Will cause severe skin and eye irritation and even burns. Eye contact can cause damage to the cornea and possibly affect visual acuity. INGESTION: May cause vomiting and nausea. Large doses can cause adverse systemic effects. | | | | |
| Carcinogenicity | NTP Listed? | IARC Cancer Review Group? | OSHA Regulated? | Target Organs? |
| Unknown Human Unknown Animal | No | No | No | Respiratory system; skin; eyes. |
| Medical Conditions Generally Aggravated by Exposure None reported. However, pre-existing lung ailments or skin disorders may be aggravated by exposure. | | | | |
| Emergency and First-aid Procedures <u>Eye contact:</u> Flush immediately with water for 15 minutes (minimum); seek medical attention. <u>Skin contact:</u> Remove all contaminated clothing. Immediately wash area with large amounts of soap and water. Seek medical assistance. For <u>inhalation:</u> Remove the person from exposure. Provide respiratory assistance and CPR. Transfer to medical facility. Observe for 24-48 hours for lung effects (pulmonary edema). If <u>swallowed:</u> Seek medical attention immediately. Call poison control center for advice. | | | | |
| SECTION VII - PRECAUTIONS FOR SAFE HANDLING AND USE | | | | |
| Steps to be Taken in Case Material is Released or Spilled Contain spills using absorbent material (vermiculite, or other). Ventilate area of spill. Remove all potential ignition sources. Store materials in DOT-approved containers. Restrict those not involved in cleanup from entering area. Notify appropriate authorities, as required. | | | | |
| Preferred Waste Disposal Method Burn in a chemical incinerator equipped with an afterburner and scrubber. | | | | |
| Precautions to be Taken in Handling and Storage Do not store with incompatible chemicals. Store in tightly closed containers in a cool, dark, well-ventilated area. Use explosion-proof equipment in areas where isobutyraldehyde is used or stored. Keep heat, fire, and flame away. If possible, automatically transfer liquids between containers. | | | | |
| Other Precautions and Warnings Bulk storage of isobutyraldehyde is not recommended. Use non-sparking tools and equipment. | | | | |
| SECTION VIII - CONTROL MEASURES AND PERSONAL PROTECTIVE EQUIPMENT | | | | |
| Respiratory Protection (<i>specify type</i>) No exposure limits have been established. This does not mean that unprotected exposure to isobutyraldehyde is permissible. For high exposures, use a self-contained breathing apparatus (SCBA) with full facepiece and pressure demand or other positive pressure mode. | | | | |
| Ventilation Local exhaust or general mechanical systems recommended. | | | | |
| Protective Gloves Impervious Material | | Eye Protection Chemical Goggles or Face Mask | | Other Protective Clothing Impermeable Apron |
| Work/Hygiene Practices Always wash hands thoroughly after using chemical; never bring food, drink, or smoking materials into vicinity of chemicals. | | | | |

ISOBUTYRALDEHYDEC₃H₇CHO

CAS: 78-84-2

**IDENTIFICATION AND TYPICAL USES**

Isobutyraldehyde is a clear, colorless mobile liquid with a pungent odor. It is used as an intermediate for rubber antioxidants and accelerators, for neopentyl glycol, in the synthesis of amino acids, in cellulose esters, and it is a perfume, flavor, resin, and gasoline additive.

RISK ASSESSMENT: HEALTH**General Assessment**

Isobutyraldehyde is moderately toxic by *ingestion*, *inhalation*, and by skin contact, although dermal absorption has not been reported. The effect of exposure to isobutyraldehyde is primarily narcotic. There are no reports on its carcinogenic, mutagenic, or teratogenic capabilities.

Inhalation may cause irritation of the nose and throat with possible nausea, vomiting, headaches, and loss of consciousness. High or prolonged exposures cause dizziness, delayed hypersensitivity, and light-headedness. Such exposures may also cause fluid to buildup in the lungs (a condition known as pulmonary edema), which is a medical emergency and can be fatal. Symptoms of pulmonary edema may be delayed up to 48 hours, thereby creating a false sense of security with regard to exposure risk.

Isobutyraldehyde is a mild skin and eye irritant. However, prolonged contact may result in burns to the skin and eyes. Eye contact can also cause severe irritation and possible damage. If ingested, isobutyraldehyde can cause gastrointestinal irritation and may lead to toxic systemic effects. The data on the effects of human exposure are somewhat limited in the references and caution is therefore warranted whenever working with or around isobutyraldehyde.

☠ Acute Health Effects

The following acute (short-term) health effects may occur immediately or shortly after exposure to isobutyraldehyde:

- Skin:** Irritation and possible burns.
- Eye:** Irritation and possible burns which can lead to injury and permanent damage if allowed to remain in contact with the eyes.
- Lung:** Irritation of the nose, throat and lungs. Can cause pulmonary edema (fluid buildup in the lungs) which can be fatal.
- CNS:** Insufficient evidence of nerve action on acute exposures. However, it is reported that exposures to high levels result in an anesthetic effect on test animals.

☘ Chronic Health Effects

The following chronic (long-term) health effects may occur at some time after exposure to isobutyraldehyde and can last for months or even years:

- Cancer Hazards:** According to the references, isobutyraldehyde has not been adequately tested for its ability to cause cancer in test animals.
- Reproduction:** According to the references, isobutyraldehyde has not been adequately tested for its ability to adversely affect reproduction in test animals.
- Other Chronic Effects:** Isobutyraldehyde has not been tested for other chronic (long-term) health effects.

🛡 Recommended Risk-Reduction Measures

Personnel should avoid direct contact with isobutyraldehyde, especially skin and eye contact. The best risk reduction measure is to use a less toxic chemical as a

substitute for a isobutyraldehyde. If this is not possible or feasible, then *engineering controls* are the most effective method of reducing exposures. The best protection is to enclose operations and/or provide local exhaust ventilation at the site of chemical release. While not always operationally feasible, isolating operations can also reduce exposure risk.

Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around isobutyraldehyde. No exposure levels have been established for this chemical. However, this does not mean that unprotected exposure is acceptable. For low level, infrequent exposures, an MSHA/NIOSH-approved chemical respirator with an organic vapor cartridge should be used. For higher exposures or when exposure levels are not known, a self-contained breathing apparatus (SCBA) with full facepiece operated in pressure demand or a powered air-purifying respirator operated in continuous flow mode are the recommended respiratory protection methods of choice. If a full facepiece is not available, then chemical goggles should be worn to protect the eyes. Whenever a chemical splash hazard exists, a face shield and a protective apron should be worn. To prevent hand and skin exposures, impervious gloves should be used. Glove manufacturers should be contacted and permeation studies obtained *before* final glove selections have been made.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with isobutyraldehyde.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where isobutyraldehyde is used or stored.

If symptoms develop or overexposure is suspected, the following medical tests are recommended:

- Consider chest X-ray after acute exposure (may be negative if taken immediately following exposure due to delayed onset of pulmonary edema).

Any medical evaluation should include a careful history of past and present symptoms with an examination. Medical tests that look for existing damage are not a substitute for controlling exposures. Also, since smoking can cause heart disease, lung cancer, emphysema, and other respiratory diseases, smokers exposed to isobutyraldehyde may experience symptoms more

rapidly than non-smokers under the same conditions of exposure. Prudent risk management requires the proper consideration of *all* possible factors which may be causing the appearance of exposure symptoms in the workplace.

Other methods to reduce exposure include:

- Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not used, respiratory protection should be mandatory.
- Always ensure that proper protective clothing is worn when using chemical substances.
- Wash thoroughly immediately after exposure to isobutyraldehyde and at the end of the work shift or before eating, drinking, or smoking.
- Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of isobutyraldehyde should be communicated to all exposed or potentially exposed workers.
- Never eat, drink, or smoke in areas where isobutyraldehyde is used, handled, or stored.
- Where possible, automatically pump liquid isobutyraldehyde from drums or other containers to process containers.
- Before entering a confined space where isobutyraldehyde may be present, verify that an explosive concentration does not exist.

RISK ASSESSMENT: ENVIRONMENT

General Assessment

The environment is at risk of exposure during transportation, storage, disposal, or destruction of isobutyraldehyde. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance.

Accidental spills, large or small, can result in fire, explosion, and possible contamination of the surrounding environmental mediums (water, soil, and air). Isobutyraldehyde is considered a Class IB flammable liquid (according to OSHA 29 CFR 1910.106) which presents a serious fire hazard concern. Also, because it is incompatible with a number of common materials, especially strong oxidizers (such as perchlorates, peroxides, permanganates, chlorates, and nitrates), contact can result in violent and explosive re-

actions. It can also form explosive mixtures in air. These characteristics require special consideration during any emergency situation involving a leak or spill of isobutyraldehyde.

Isobutyraldehyde can enter the environment as a result of unchecked industrial discharges into effluents and through spills.

☠ *Acute Ecological Effects*

Acute (short-term) toxic effects may include the death of animals, birds, or fish, and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to isobutyraldehyde. This chemical has moderate acute toxicity to aquatic life. Insufficient data are available to evaluate or predict the short-term effects of isobutyraldehyde to plants, birds, or terrestrial animals.

🕒 *Chronic Ecological Effects*

Chronic toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals. Isobutyraldehyde has moderate chronic toxicity to aquatic life. Insufficient data are available to evaluate or predict the long-term effects of isobutyraldehyde to plants, birds, or land animals.

💧 *Water Solubility*

Isobutyraldehyde is highly soluble in water. Concentrations of 1000 milligrams and more will mix with a liter of water.

🕒 *Persistence in the Environment*

Isobutyraldehyde is slightly persistent in water, with a half-life of between 2 to 20 days. The half-life of a pollutant is the amount of time it takes for one-half of the chemical to be degraded. Approximately 88% of isobutyraldehyde that will eventually end up in air with the remainder ending up in water.

🌊 *Bioaccumulation in Aquatic Organisms*

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans.

The concentration of isobutyraldehyde found in fish tissues is expected to be about the same the average concentration of isobutyraldehyde in water from which the fish was taken.

🔧 *Recommended Risk-Reduction Measures*

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in a leak or spill to the environment. The correct use of DOT labeling (per the MSDS) on all containers, trucks, and rail cars will enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of isobutyraldehyde should be segregated from incompatible chemicals to minimize the risk of cross-contamination or contact. Buildings designated for storage should be equipped with appropriate fire protection systems (alarms, sprinklers, emergency lighting, portable extinguishers). Explosion-proof equipment is recommended in areas where isobutyraldehyde is used, handled, or stored.

If a spill or leak to the environment has occurred, fire department, emergency response, and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those trained in proper spill containment procedures using non-sparking tools. Contaminated soils should be removed for incineration and replaced with clean soil.

If isobutyraldehyde should contact the water table, aquifer, or navigable waterway, time is of the essence. It is highly soluble in water and, therefore, total containment and remediation may not be possible. When such spills occur, the local and/or state emergency response authorities must be notified. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of isobutyraldehyde. If isobutyraldehyde is spilled or leaked, the following specific steps are recommended:

- Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened for normal work.
- Remove all ignition sources.
- Ventilate area of spill or leak.
- Absorb liquids in vermiculite, dry sand, earth, or a similar material and deposit in sealed containers.
- It may be necessary to dispose of isobutyraldehyde as a hazardous waste. The responsible state

agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving isobutyraldehyde can present a serious threat to business operations. The loss or damage of equipment or facilities can significantly affect fiscal viability. Lawsuits that may result from personnel injury/death, public exposures, and/or environmental contamination will also require a serious expenditure of resources. Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business.

Recommended Risk-Reduction Measures

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures or policies intended to manage the use of chemicals in the workplace. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

| SECTION V - REACTIVITY DATA | | | | |
|---|----------------------------|---|--------------------------------|---|
| Stability | | Conditions to Avoid Isobutyronitrile is normally stable in closed containers under routine conditions of storage and handling. Avoid contact with incompatible materials or exposure to excessive heat, sparks, or flame. | | |
| Stable X | Unstable | Incompatibility (<i>materials to avoid</i>) Incompatible with strong oxidizers (such as chlorine, bromine, fluorine, perchlorates, nitrates, permanganates), and other oxidizable materials. | | |
| Hazardous Polymerization | | Conditions to Avoid Under normal conditions of temperature and pressure, hazardous polymerization of isobutyronitrile is not expected to occur. | | |
| May Occur | Will Not Occur X | Hazardous Decomposition or By-products When heated to decomposition, isobutyronitrile emits highly toxic fumes of nitrogen oxide as well as cyanide gas. | | |
| SECTION VI - HEALTH HAZARD DATA | | | | |
| Primary Route(s) of Entry: | | Inhalation? X | Absorption (skin)? X | Ingestion? X |
| Health Hazards | | | | |
| INHALATION: Will cause irritation of the respiratory tract with symptoms of cyanide poisoning. These include seizures, dilated pupils, shock, reduced respiration, cyanosis, initial tachycardia (rapid heartbeat) and hypertension (high blood pressure) followed by hypotension (low blood pressure) and subsequent loss of consciousness and coma. There can also be symptoms of nausea, vomiting, liver injury, acidosis, and death (asphyxiation). | | | | |
| ABSORPTION: Skin contact can result in irritating rash. Can cause severe eye burns and/or irritation with conjunctivitis. Will pass through intact skin to cause systemic effects. | | | | |
| INGESTION: Irritation of the digestive tract and toxic systemic effects (reference inhalation above). | | | | |
| Carcinogenicity | NTP Listed? | IARC Cancer Review Group? | OSHA Regulated? | Target Organs? |
| Unknown Human Unknown Animal | No | No | No | Liver, CNS, respiratory tract, skin, eyes. |
| Medical Conditions Generally Aggravated by Exposure Respiratory impairments, (asthma); skin conditions (dermatitis); liver dysfunction. | | | | |
| Emergency and First-aid Procedures | | | | |
| Eye contact: Flush immediately with water for 15 minutes (minimum); seek medical attention. Skin contact: Remove all contaminated clothing. Immediately wash area with large amounts of soap and water. Seek medical assistance. For inhalation: Remove the person from exposure. Provide respiratory assistance and CPR. Transfer to medical facility. Isobutyronitrile can cause fatal cyanide poisoning. If swallowed: Give conscious person 1-2 glasses of water to dilute. Do Not induce vomiting. | | | | |
| SECTION VII - PRECAUTIONS FOR SAFE HANDLING AND USE | | | | |
| Steps to be Taken in Case Material is Released or Spilled | | | | |
| Contain spills using absorbent material (vermiculite, or other). Ventilate area of spill and remove all ignition sources. Have water source available in case of fire. Store materials in DOT-approved containers. Restrict those not involved in cleanup from entering area. | | | | |
| Preferred Waste Disposal Method | | | | |
| Burn in chemical incineration equipped with an afterburner and scrubber. | | | | |
| Precautions to be Taken in Handling and Storage | | | | |
| Store in tightly closed containers in cool, well-ventilated area away from heat. Storage drums should have self-closing valves, pressure vacuum bungs, and flame arresters. | | | | |
| Other Precautions and Warnings | | | | |
| Bulk storage of isobutyronitrile is not recommended. | | | | |
| SECTION VIII - CONTROL MEASURES AND PERSONAL PROTECTIVE EQUIPMENT | | | | |
| Respiratory Protection (<i>specify type</i>) | | | | |
| No exposure levels have been established and the specific toxicity of this chemical is unclear. The best protection is obtained using a self-contained breathing apparatus (SCBA) or a supplied-air respirator with full facepiece operated in pressure demand or other positive pressure mode. | | | | |
| Ventilation | | | | |
| Local exhaust or general mechanical systems recommended. | | | | |
| Protective Gloves | | Eye Protection | | Other Protective Clothing |
| Impervious Material | | Chemical Goggles or Face Mask | | Protective Apron |
| Work/Hygiene Practices | | | | |
| Always wash hands thoroughly after using chemical; never bring food, drink, or smoking materials into vicinity of chemicals. | | | | |

ISOBUTYRONITRILE

CAS: 78-82-0

**IDENTIFICATION AND TYPICAL USES**

Isobutyronitrile is a colorless liquid with an almond-like odor. It is used as an intermediate for insecticides, in organic synthesis, in some plastics and synthetic fibers, and as a gasoline additive.

RISK ASSESSMENT: HEALTH**General Assessment**

Human exposure to isobutyronitrile can occur through three routes of entry into the body: *inhalation*, *absorption*, and *ingestion*. The toxic effects of isobutyronitrile are attributed to the metabolic release of cyanide, which in turn acts by inhibiting cytochrome oxidase and thus impairs cellular respiration. The target organs are the liver, central nervous system (CNS), lungs, skin, and eyes. Isobutyronitrile causes headache, dizziness, and nausea. At extremely high concentrations, it can cause convulsions, coma, and death. There are no data in the references on the chemical's carcinogenicity, mutagenicity, or teratogenicity in humans.

In humans, inhalation of isobutyronitrile vapors can result in systemic symptoms as those for cyanide. These include seizures, dilated pupils, shock, decreased respiration, cyanosis (due to lack of oxygenated blood), initial tachycardia (rapid heartbeat) and hypertension followed by low blood pressure and coma. There can be asphyxia, liver toxicity, acidosis, nausea, vomiting, and tightness of the chest. Death can occur as a result of asphyxiation as a result of blockage of respiratory enzymes. It is excreted in the urine as a cyanate. The blood cyanide concentration does not always show any significant increase in cyanide at low exposure concentrations.

Ingestion of isobutyronitrile results in gastrointestinal pain, nausea, vomiting, stupor, convulsion, weakness, and other similar systemic effects. Large doses can be fatal. Skin contact results in absorption and systemic effects. Severe eye irritation is likely.

☠ Acute Health Effects

The following acute (short-term) health effects may occur immediately or shortly after exposure to isobutyronitrile. (Note: Exposure can cause fatal cyanide poisoning. Symptoms of flushing of face, chest tightness, nausea, and vomiting, weakness, and shortness of breath may lead to death. These reactions may begin minutes or hours after an overexposure).

Skin: Irritation/rash on contact (contact dermatitis).

Eye: Severe irritation, conjunctivitis, damage.

Lung: Irritation of the nose, throat, and lungs following exposure.

CNS: High concentrations may cause severe depression of the central nervous system with sleepiness, dizziness, loss of consciousness, or death.

☘ Chronic Health Effects

The following chronic (long-term) health effects may occur at some time after exposure to isobutyronitrile and can last for months or even years:

Cancer Hazards: According to the references, isobutyronitrile has not been tested for its ability to cause cancer in animals. Chronic effects of high exposures have not been documented in humans.

Reproductive Hazard: According to the references, isobutyronitrile has not been significantly tested for its ability to adversely affect reproduction.

Other Chronic Effects: High exposures may damage the nervous system, liver, and kidneys. Very irritating substances may affect the lungs. It is not known whether isobutyronitrile causes lung damage.

🛡 Recommended Risk-Reduction Measures

Personnel should avoid direct contact with isobutyronitrile. Unless a less toxic chemical can be substituted for a hazardous substance, *engineering controls*

are the most effective method of reducing exposures. The best protection is to enclose operations and/or provide local exhaust ventilation at the site of chemical release. While not always operationally feasible, isolating operations can also reduce exposure. Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around isobutyronitrile. No exposure levels have been established for this compound. This does not mean that exposure is without risk. For any exposure, recommend using a self-contained breathing apparatus (SCBA) with full facepiece operated in pressure demand or a supplied-air respirator operated in continuous flow mode are the recommended respiratory protection methods of choice. If a full facepiece is not available, then chemical goggles should be worn to protect the eyes. Whenever a chemical splash hazard exists, a face shield and a protective apron should be worn. To prevent hand and skin exposures, impervious gloves should be used. Glove manufacturers should be contacted and permeation studies obtained *before* final glove selections have been made.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with isobutyronitrile.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where isobutyronitrile is used or stored.

Medical testing of personnel with frequent or potentially high exposure (half the PEL or greater), should be offered before beginning work and at regular intervals thereafter. These tests should include:

- ☑ Lung function (pulmonary function) test.

If symptoms develop or overexposure is suspected, the following tests may be useful:

- ☑ Blood cyanide test and/or urine thiocyanate test (currently, a blood cyanide level over 0.1 mg/l or urine thiocyanate over 20 mg/l indicates overexposure).
- ☑ Maintain close medical surveillance. Slow release of cyanide from absorbed isobutyronitrile may cause delayed symptoms.
- ☑ Liver function tests.
- ☑ Kidney function tests.

Other methods to reduce exposure include:

- ☑ Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not used, respiratory protection should be mandatory.
- ☑ Always ensure that proper protective clothing is worn when using chemical substances.
- ☑ Wash thoroughly immediately after exposure to isobutyronitrile and at the end of the work shift or before eating, drinking, or smoking.
- ☑ Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of isobutyronitrile should be communicated to all exposed or potentially exposed workers.

RISK ASSESSMENT: ENVIRONMENT

General Assessment

The environment is at risk of exposure during transportation, storage, disposal, or destruction of isobutyronitrile. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance. Accidental spills, large or small, can result in fire, explosion, and possible contamination of the surrounding environmental mediums (water, soil, and air).

Isobutyronitrile is considered a highly flammable liquid and a poison. Because of its low flash point and high boiling point, it is classified as a Class 1B flammable liquid (per OSHA 29 CFR 1910.106). Isobutyronitrile vapors form explosive mixtures in air. It reacts with strong oxidizers, liberating heat along with pressure increase. Thus, contact under closed conditions can cause explosion. These characteristics require special consideration during any emergency situation involving a leak or spill of isobutyronitrile. Should isobutyronitrile ever come into contact with incompatible substances either during use, transportation, or storage, the formation of highly toxic and/or highly explosive commodities is extremely possible.

The proper disposal/destruction method for isobutyronitrile is to burn it in a chemical incinerator equipped with an afterburner and air scrubber.

Isobutyronitrile can enter the environment through manufacturing effluents, municipal waste treatment discharges, and spills.

☠ *Acute Ecological Effects*

Acute (short-term) toxic effects may include the death of animals, birds, or fish and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to isobutyronitrile.

This chemical has slight acute toxicity to aquatic life. No data are available on the short-term effects of isobutyronitrile to plants or land animals.

🕒 *Chronic Ecological Effects*

Chronic toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals.

Isobutyronitrile has slight chronic toxicity in aquatic life. No data are available on the long-term effects of isobutyronitrile to plants, birds, or land animals.

💧 *Water Solubility*

Isobutyronitrile is slightly soluble in water. Concentrations of 1 to 100 milligrams will mix with a liter of water.

🕒 *Persistence in the Environment*

Isobutyronitrile is slightly persistent in water, with a half-life of between 2 to 20 days. The half-life of a pollutant is the amount of time it takes for one half of the chemical to be degraded.

🐟 *Bioaccumulation in Aquatic Organisms*

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans.

The concentration of isobutyronitrile found in fish tissues is expected to be about the same as the average concentration of isobutyronitrile in water from which the fish was taken.

🛡️ *Recommended Risk-Reduction Measures*

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in a leak or spill to the environment. The correct use of DOT labeling (per the MSDS) on all containers, trucks, and rail cars will enable emergency responders to react

properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of isobutyronitrile should be segregated from incompatible chemicals to minimize the risk of cross-contamination or contact. Buildings designated for storage should be equipped with appropriate fire protection systems (alarms, sprinklers, emergency lighting, portable extinguishers).

If a spill or leak to the environment has occurred, fire department, emergency response, and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those trained in proper spill containment procedures using non-sparking tools. Contaminated soils should be removed for incineration and replaced with clean soil. If isobutyronitrile should contact the water table, aquifer, or navigable waterway, time is of the essence. It is readily miscible in water and, therefore, total containment and remediation may not be entirely possible. When such spills occur, the local and/or state emergency response authorities must be notified. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of isobutyronitrile. If isobutyronitrile is spilled or leaked, the following specific steps are recommended:

- ☑ Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened for normal work.
- ☑ Remove ignition sources and ventilate area.
- ☑ Absorb liquids in vermiculite, dry sand, earth, or a similar material and deposit in sealed containers. Use non-sparking tools during cleanup.
- ☑ It may be necessary to dispose of isobutyronitrile as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving isobutyronitrile can present a significant threat to business operations. The loss or damage of equipment or facilities can significantly affect fiscal viability. Lawsuits that may result from personnel injury/death, public exposures, and/or environmental contamination will also require a serious expenditure of resources. Media attention

surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business.

U Recommended Risk-Reduction Measures

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures dealing with safety or emergency response. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

ISOPENTANE

CAS: 78-78-4

**IDENTIFICATION AND TYPICAL USES**

Isopentane is a colorless, mobile liquid with a pungent, sweet odor. It is used primarily as a solvent and in the manufacture of certain chlorinated derivatives. It is also a blowing agent for polystyrene.

RISK ASSESSMENT: HEALTH**General Assessment**

Isopentane is an acute irritant of low-order toxicity by *inhalation* and *ingestion*. Skin contact can also produce some adverse topical effects. It is generally considered to be a safe solvent for industrial use when used according to manufacturer's instructions. However, in sufficient or high concentrations, there can be toxic systemic effects through both routes of exposure. There are no data on its carcinogenic, mutagenic, or teratogenic capabilities.

Significant inhalation may cause irritation of the respiratory tract and depress the central nervous system. Symptoms include cough, irregular heartbeat, and mild depression with nausea, dizziness, vomiting, and a possibility of pulmonary edema (fluid in the lungs). Development of pulmonary edema can be delayed up to 48 hours thereby creating a false sense of security with regard to health exposure risk. At high concentrations, it is a narcotic and can lead to coma and death due to respiratory failure. It has low chronic toxicity due to its efficient metabolism and excretion.

Skin and eye contact may produce mild to moderate irritation on contact. Repeated or prolonged contact with the skin can lead to drying, cracking, chapping, and secondary infection and/or dermatitis.

Ingestion can produce narcotic effects as those noted for inhalation above. Aspiration results in lung

irritation, pulmonary edema, chemical pneumonitis, coughing, and central nervous system effects.

☠ Acute Health Effects

The following acute (short-term) health effects may occur immediately or shortly after exposure to isopentane:

Skin: Mild irritation on contact. Can cause drying and cracking if not removed promptly.

Eye: Mild to moderate irritation.

Lung: Mild to moderate irritation of the nose, throat, mucosa, and respiratory tract causing cough and tightness in chest. May cause dizziness, vomiting, and nausea. Primary result of inhalation of isopentane is its action on the CNS.

CNS: A CNS depressant causing headache, dizziness, depression, and narcotic effects through inhalation or ingestion.

☘ Chronic Health Effects

The following chronic (long-term) health effects may occur at some time after exposure to isopentane and can last for months or even years:

Cancer Hazards: According to information presented in the references, isopentane has not been adequately tested for its ability to cause cancer in animals. Limited studies indicate an increased incidence of Hodgkin's disease in workers exposed to organic solvents. It is not known, however, whether isopentane will have this effect.

Reproductive Hazard: According to information presented in the references, isopentane has not been tested for its ability to adversely affect reproduction.

Other Chronic Effects: Prolonged skin contact may cause drying, cracking, and chapping of the affected area creating the potential for secondary infection and/or dermatitis.

🔍 **Recommended Risk-Reduction Measures**

Personnel should avoid direct contact with isopentane. Even though the toxicity of this chemical is considered to be of relatively low order, it can still cause significant health effects if improperly used or if over-exposures occur. If a less toxic chemical cannot be substituted for a hazardous substance, then *engineering controls* are the most effective method of reducing exposures. The best protection is to enclose operations and/or provide local exhaust ventilation at the site of chemical release. While not always operationally feasible, isolating operations can also reduce exposure. Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around isopentane. For exposures above the PEL (600 ppm), an air-purifying respirator with an organic vapor cartridge should be used. Better protection is obtained using a supplied-air respirator with full facepiece operated in continuous flow mode, or a self-contained breathing apparatus (SCBA) with full facepiece and pressure demand or other continuous flow mode. If a full facepiece is not available, then chemical goggles should be worn to protect the eyes. Whenever a chemical splash hazard exists, a face shield and a rubber apron should be worn. To prevent hand and skin exposures, impervious gloves should be used. Glove manufacturers should be contacted and permeation studies obtained *before* final glove selections have been made.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with isopentane.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where isopentane is used or stored.

If symptoms develop or overexposure is suspected, the following tests are recommended:

- Lung function tests.
- Consider chest X-ray following acute overexposure (may be negative if taken immediately after exposure due to delayed onset of pulmonary edema).

Any evaluation should include a careful history of past and present symptoms with an examination. Medical tests that simply look for existing damage are not a substitute for controlling exposures. Also, since smoking can cause heart disease, lung cancer, emphysema, and other respiratory diseases, smokers exposed to isopentane may experience symptoms more rapidly than non-smokers under the same conditions of exposure. Prudent risk management requires proper consideration of *all* possible factors which may be causing the appearance of exposure symptoms in the workplace.

Other methods to reduce exposure include:

- Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not used, respiratory protection should be mandatory.
- Always ensure that proper protective clothing is worn when using chemical substances.
- Wash thoroughly immediately after exposure to isopentane and at the end of the work shift or before eating, drinking, or smoking.
- Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of isopentane should be communicated to all exposed workers.
- Eye wash stations should be provided in the immediate work area for emergency use. If there is a possibility of skin exposure to isopentane, emergency shower facilities should also be provided.
- Personnel should never wear contaminated clothing home (family members can be exposed). Clothing should be laundered by personnel who have been trained on the hazards of isopentane.

RISK ASSESSMENT: ENVIRONMENT

General Assessment

The environment is at risk of exposure during transportation, storage, disposal, or destruction of isopentane. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance. Accidental spills, large or small, can result in fire, explosion, and possible contamination of the surrounding environmental mediums (water, soil, and air).

Isopentane is considered a Class 1A flammable liquid (per OSHA 29 CFR 1910.106). Its extremely low flash point and relatively low boiling point make this chemical a serious fire and explosion hazard concern. These characteristics require extreme caution in handling, storage, transportation, and disposal. It is incompatible with common peroxides and other oxidizers and contact can cause fire or explosion. Therefore, special consideration is required during any emergency situation involving a leak or spill of isopentane. Should isopentane ever come into contact with these incompatible substances during use, transportation, storage, or disposal, the formation of highly toxic and/or highly explosive commodities (including hydrogen chloride) is extremely possible.

Isopentane may enter the environment through industrial discharges or spills.

☠ *Acute Ecological Effects*

Acute (short-term) toxic effects may include the death of animals, birds, or fish and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to isopentane.

This chemical has high acute toxicity to aquatic life. Insufficient data are available on the short-term effects of isopentane exposure to aquatic life, birds or land animals.

🕒 *Chronic Ecological Effects*

Chronic (long-term) toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals.

Isopentane has moderate chronic toxicity in aquatic life. Insufficient data are available on the long-term effects of isopentane to plants, birds, or land animals.

💧 *Water Solubility*

Isopentane is nearly insoluble in water. Concentrations of less than 100 milligrams may mix with a liter of water, depending on water pH and chemical concentration of isopentane.

🕒 *Persistence in the Environment*

Isopentane is non-persistent in water, with a half-life of less than 2 days. The half-life of a pollutant is the amount of time it takes for one half of the chemical to

be degraded. Virtually 100% of isopentane will eventually end up in air.

🐟 *Bioaccumulation in Aquatic Organisms*

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans.

The concentration of isopentane found in fish tissue is expected to be somewhat lower than the average concentration of isopentane in the water from which the fish was taken.

🛡️ *Recommended Risk-Reduction Measures*

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in a leak or spill to the environment. The correct use of DOT labeling (per the MSDS) on all containers, trucks, and rail cars will enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of isopentane should be segregated from incompatible chemicals to minimize the risk of cross-contamination or contact. Buildings designated for storage should be equipped with appropriate fire protection systems (alarms, sprinklers, emergency lighting, portable extinguishers). Electrical equipment should be design to meet applicable explosion-proof requirements.

If a spill or leak to the environment has occurred, fire department, emergency response and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those trained in proper spill containment procedures using non-sparking tools. Contaminated soils should be removed for incineration and replaced with clean soil. If isopentane should contact the water table, aquifer, or navigable waterway, the local and/or state emergency response authorities must be notified. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of isopentane. If isopentane is spilled or leaked, the following specific steps are recommended:

- Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened for normal work.
- Remove all ignition sources.

- ☑ Ventilate area of spill or leak using explosion-proof ventilation system, if possible.
- ☑ For small spills (laboratory spills), absorb liquid in paper towels. Allow evaporation in a safe place (a fume hood or open air). After sufficient time has passed for evaporation, burn paper towels away from other combustibles. For larger spills, absorb liquids in vermiculite, dry sand, earth, or similar material and deposit in sealed containers.
- ☑ It may be necessary to dispose of isopentane as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving isopentane can present a significant threat to business operations. The loss or damage of equipment or facilities can significantly affect fiscal viability. Lawsuits that may result from personnel injury/death, public exposures, and/or environmental contamination will also require a serious expenditure of resources. Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business.

Recommended Risk-Reduction Measures

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures dealing with safety or emergency response. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

| Special Fire Fighting Procedures Wear full protective clothing and self-contained breathing apparatus (SCBA). Poisonous gases are produced in fire. Use water spray to keep fire-exposed containers cool. Containers may explode in fire. | | | | | | |
| Unusual Fire and Explosion Hazards Combustible liquid but a dangerous fire hazard when exposed to heat. At high temperatures, forms explosive mixtures with air. Violent reactions can occur with nitric acid. Chemical will react on contact with oxidizable materials. Moderate explosion hazard when in the form of vapor. | | | | | | |

| SECTION V - REACTIVITY DATA | | | | |
|--|----------------------------|---|--|---|
| Stability | | Conditions to Avoid Normally stable. Keep away from sources of heat (including direct sunlight) or flame. Large quantities should be stored in metal tanks or drums. Keep away from incompatible materials. | | |
| Stable X | Unstable | Incompatibility (<i>materials to avoid</i>) Strong oxidizers (permanganates, peroxides, nitrates, chlorates, and perchlorates), acids (nitric and sulfuric), strong alkalis, and amines. | | |
| Hazardous Polymerization | | Conditions to Avoid Under normal conditions of temperature and pressure, hazardous polymerization of isophorone is not expected to occur. | | |
| May Occur | Will Not Occur X | Hazardous Decomposition or By-products When heated to decomposition, isophorone can emit highly toxic/poisonous and acrid fumes and gases including oxides of carbon. | | |
| SECTION VI - HEALTH HAZARD DATA | | | | |
| Primary Route(s) of Entry: | | Inhalation? X | Absorption (skin)? | Ingestion? X |
| Health Hazards INHALATION: Symptoms include irritation of the eyes, nose, throat, and respiratory system. May cause depression of the central nervous system with narcosis, inebriation, headache, fatigue, malaise, and dizziness. Liver and kidney damage are also possible. Other effects include olfactory changes, faintness, suffocation, tearing, and possible pulmonary edema. SKIN & EYES: Irritating to the skin; may cause irritation and dermatitis. An eye irritant with possibility of corneal opacity and damage. INGESTION: Irritation of the mouth and stomach, narcosis, anesthesia, and respiratory difficulties. | | | | |
| Carcinogenicity Unknown Human Questioned Animal | NTP Listed? No | IARC Cancer Review Group? No | OSHA Regulated? 29 CFR 1910.1000 Table Z-1 | Target Organs? Respiratory system, eyes, skin, kidney, liver. |
| Medical Conditions Generally Aggravated by Exposure None reported. | | | | |
| Emergency and First-aid Procedures Eye contact: Flush immediately with water for 15 minutes (minimum); seek medical attention. Skin contact: Remove all contaminated clothing. Immediately wash area with large amounts of soap and water. Seek medical assistance. For inhalation: Remove the person from exposure. Provide respiratory assistance and CPR, if required. Transfer to medical facility. Keep victim warm and at rest. Observe for 24-48 hours for lungs effects (pulmonary edema). If swallowed: Seek medical attention immediately. Give 1-2 glasses of water to drink. Do NOT induce vomiting (aspiration hazard). | | | | |
| SECTION VII - PRECAUTIONS FOR SAFE HANDLING AND USE | | | | |
| Steps to be Taken in Case Material is Released or Spilled Absorb in vermiculite, earth, or similar material and deposit in sealed containers. Ventilate area of spill or leak. Restrict those not involved in cleanup from entering area. Remove all sources of ignition. | | | | |
| Preferred Waste Disposal Method Burn in chemical incinerator equipped with an afterburner and scrubber. | | | | |
| Precautions to be Taken in Handling and Storage Store to avoid contact with incompatible materials in tightly closed containers in cool, well-ventilated area away from heat and flame. Use only non-sparking tools to open and close containers. | | | | |
| Other Precautions and Warnings Sources of ignition are prohibited where isophorone is used, handled, or stored. Heat may cause containers to build up pressure and explode. Containers must be grounded and bonded during transfer. | | | | |
| SECTION VIII - CONTROL MEASURES AND PERSONAL PROTECTIVE EQUIPMENT | | | | |
| Respiratory Protection (<i>specify type</i>) For exposures above the PEL, use an MSHA/NIOSH-approved supplied-air respirator with full facepiece, hood, or helmet in continuous flow mode, or use a self-contained breathing apparatus (SCBA) operated in pressure demand or other positive pressure mode. | | | | |
| Ventilation Local exhaust or general mechanical systems recommended. | | | | |
| Protective Gloves Impervious Material | | Eye Protection Chemical Goggles or Face Mask | | Other Protective Clothing Impervious Apron |
| Work/Hygiene Practices Always wash hands thoroughly after using chemical; never bring food, drink, or smoking materials into vicinity of chemicals. | | | | |

ISOPHORONEC₉H₁₄O

CAS: 78-59-1

**IDENTIFICATION AND TYPICAL USES**

Isophorone is a clear or colorless liquid with an acetone, peppermint, or camphor-like odor. It is used in solvent mixtures for finishes, for polyvinyl and nitrocellulose resins, in pesticides, and in stoving lacquers.

RISK ASSESSMENT: HEALTH***General Assessment***

Isophorone is moderately toxic by *ingestion* and skin contact (although absorption through intact skin has not been reported). It is also mildly toxic to humans by *inhalation*. Because of its low volatility, its vapors are not often present at dangerous levels in the workplace, unless heated or misted. Its carcinogenicity in humans is not known but is questioned in some animal studies. It is primarily a kidney poison. It has been shown to cause mutations (genetic changes) in living cells.

Inhalation can cause changes in the sense of smell, conjunctiva irritation, and possible respiratory changes. It will irritate the nose, throat, and eyes and fatigue the sense of smell. It may also cause a dangerous buildup of fluid in the lungs (pulmonary edema) which is a medical emergency and can be fatal. Symptoms can be delayed up to 48 hours, thereby creating a false sense of security with regard to health exposure risk. Mild narcotic properties have also been recorded, including pronounced headache, and it may cause depression of the central nervous system, although this effect is not completely confirmed in the references. Other symptoms of inhalation include CNS depression with nausea, dizziness, fatigue, malaise, narcosis, decreased breathing rate, and anesthesia. Kidney and liver damage with mild narcosis may also be possible.

Skin and eye contact may produce mild to moderate irritation on contact. Pure liquid in contact with the eye may result in corneal opacity and subsequent damage.

On ingestion, isophorone is expected to produce symptoms of irritation, nausea, vomiting, stomach pain, narcosis, anesthesia, and some respiratory difficulties.

☠ *Acute Health Effects*

The following acute (short-term) health effects may occur immediately or shortly after exposure to isophorone:

- Skin:** Will defat the skin and can cause dermatitis. Pure liquid will cause severe irritation.
- Eye:** Severe irritation with a potential for corneal injury or damage.
- Lung:** Nose and throat irritation. Produces intoxicating effects and may cause lung damage, including pulmonary edema.
- CNS:** There may be depression, anesthesia, hypothermia, narcosis, and other effects.

☠* *Chronic Health Effects*

The following chronic (long-term) health effects may occur at some time after exposure to isophorone and can last for months or even years:

Cancer Hazards: According to information presented in the references, isophorone has been shown to cause cancer in test animals. Some studies indicate that it causes mutations in living cells, while others are inconclusive in this regard. Some studies have listed its cancer causing properties as questioned animal studies. Further studies are required in this regard.

Reproductive Hazard: According to information presented in the references, isophorone has not been adequately tested for its ability to adversely affect reproduction.

Other Chronic Effects: Prolonged skin contact may cause drying, cracking, and chapping of the affected area. There may be skin sensitization and/or dermatitis in some individuals. Repeated or long-term exposures to isophorone may affect the liver and kidneys.

🔹 **Recommended Risk-Reduction Measures**

Personnel should avoid direct contact with isophorone. The exact nature of the toxicity of this chemical is not entirely clear in the references. Therefore, prudent risk management requires it be treated as though it posed a significant health risk in the event of overexposure. If a less toxic chemical cannot be substituted for a hazardous substance, then *engineering controls* are the most effective method of reducing exposures. The best protection is to enclose operations and/or provide local exhaust ventilation at the site of chemical release. While not always operationally feasible, isolating operations can also reduce exposure. Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around isophorone. It is irritating at levels above 25 ppm. For exposures above the 25 ppm PEL, a supplied-air respirator with full facepiece operated in continuous flow mode, or a self-contained breathing apparatus (SCBA) with full facepiece and pressure demand are the recommended respiratory protection methods of choice. If a full facepiece is not available, then chemical goggles should be worn to protect the eyes. Whenever a chemical splash hazard exists, a face shield and a rubber apron should be worn. To prevent hand and skin exposures, impervious gloves should be used. Glove manufacturers should be contacted and permeation studies obtained *before* final glove selections have been made.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with isophorone.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where isophorone is used or stored.

If symptoms develop or overexposure is suspected, the following tests are recommended:

- ☑ Kidney and liver function tests.
- ☑ Evaluation by a qualified allergist, with careful consideration of exposure history and special skin tests (may help diagnose allergy).
- ☑ Lung function tests, including forced vital capacity (FVC).
- ☑ Consider chest X-ray following acute overexposure (may be negative if taken immediately after exposure due to delayed onset of pulmonary edema).

Any evaluation should include a careful history of past and present symptoms with an examination. Medical tests that simply look for existing damage are not a substitute for controlling exposures. Also, since smoking can cause heart disease, emphysema, and other respiratory disorders, symptoms of exposure to isophorone may be more pronounced than those displayed by non-smokers. Proper risk assessment requires careful consideration of *all* possible factors that may be causing the appearance of symptoms in exposed workers.

Other methods to reduce exposure include:

- ☑ Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not used, respiratory protection should be mandatory. Also, if possible, automatic transfer of isophorone from storage containers to process or work containers is recommended.
- ☑ Always ensure that proper protective clothing is worn when using chemical substances.
- ☑ Wash thoroughly immediately after exposure to isophorone and at the end of the work shift or before eating, drinking, or smoking.
- ☑ Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of isophorone should be communicated to all exposed and potentially exposed workers.
- ☑ Eye wash stations should be provided in the immediate work area for emergency use. If there is a possibility of skin exposure to isophorone, emergency shower facilities should also be provided in the immediate work area.

- ☑ Personnel should never wear contaminated clothing home (family members can be exposed). Clothing should be laundered by personnel who have been trained on the hazards of isophorone.

RISK ASSESSMENT: ENVIRONMENT

General Assessment

The environment is at risk of exposure and contamination during transportation, storage, disposal, or destruction of isophorone. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance. Accidental spills, large or small, can result in fire, explosion, and possible contamination of the surrounding environmental mediums (water, soil, and air).

Isophorone is considered a Class IIIA combustible liquid (per OSHA 29 CFR 1910.106). It presents a moderate fire and explosion hazard risk, especially in contact with incompatible materials. These characteristics require extreme caution in handling, storage, transportation, and disposal. It is incompatible with common peroxides and other oxidizers and contact can cause fire or explosion. It reacts violently when added to nitric or sulfuric acid. Therefore, special consideration is required during any emergency situation involving a leak or spill of isophorone. Should isophorone ever come into contact with these incompatible substances during use, transportation, storage, or disposal, the formation of highly toxic and/or highly explosive commodities is extremely possible.

The proper disposal method for isophorone is to burn it in a chemical incinerator equipped with an afterburner and scrubber.

Isophorone may enter the environment through industrial discharges or spills.

☠ *Acute Ecological Effects*

Acute (short-term) toxic effects may include the death of animals, birds, or fish and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to isophorone.

Insufficient data are available on the short-term effects of isophorone exposure to aquatic life, birds, plants, or land animals.

🕒 *Chronic Ecological Effects*

Chronic (long-term) toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed

animals. These effects can be seen long after first exposure(s) to toxic chemicals.

Insufficient data are available on the long-term effects of isophorone exposure to aquatic life, birds, plants, or land animals.

💧 *Water Solubility*

Isophorone is nearly insoluble in water. Concentrations of less than 100 milligrams may mix with a liter of water, depending on water pH and chemical concentration of isophorone.

🕒 *Persistence in the Environment*

Isophorone is moderately persistent in water, with a half-life between 20 and 200 days. The half-life of a pollutant is the amount of time it takes for one half of the chemical to be degraded.

🐟 *Bioaccumulation in Aquatic Organisms*

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans.

The concentration of isophorone found in fish tissue is expected to be somewhat higher than the average concentration of isophorone in the water from which the fish was taken.

🛡️ *Recommended Risk-Reduction Measures*

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in a leak or spill to the environment. The correct use of DOT labeling (per the MSDS) on all containers, trucks, and rail cars will enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of isophorone should be segregated from incompatible chemicals to minimize the risk of cross-contamination or contact. Buildings designated for storage should be equipped with appropriate fire protection systems (alarms, sprinklers, emergency lighting, portable extinguishers).

If a spill or leak to the environment has occurred, fire department, emergency response and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those trained in proper spill containment procedures using non-sparking tools. Contaminated soils should be re-

moved for incineration and replaced with clean soil. If isophorone should contact the water table, aquifer, or navigable waterway, cleanup should be started immediately. It is only slightly soluble in water and total remediation may be possible. The local and/or state emergency response authorities must be notified. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of isophorone. If isophorone is spilled or leaked, the following specific steps are recommended:

- ☑ Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened for normal work.
- ☑ Remove all ignition sources; ventilate area of leak.
- ☑ Absorb liquids in vermiculite, dry sand, earth, or similar material and deposit in sealed containers.
- ☑ It may be necessary to dispose of isophorone as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving isophorone can present a significant threat to business operations. The loss or damage of equipment or facilities can significantly affect fiscal viability. Lawsuits that may result from personnel injury/death, public exposures, and/or environmental contamination will also require a serious expenditure of resources. Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business.

Recommended Risk-Reduction Measures

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures dealing with safety or emergency response. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

SECTION I - GENERAL INFORMATION

| | | |
|--|---|------------------------------------|
| Characterization Isocyanate, Organic | RCRA Number None | EPA Class Not Applicable |
| DOT Proper Shipping Name Isophorone diisocyanate | Chemical Abstract Service (CAS) Number 4098-71-9 | |
| DOT Hazard Class and Label Requirements Poison | DOT Emergency Guide Code 55 | |
| DOT Identification Number UN 2290 | Chemical Formula C₁₂H₁₈N₂O₂ | |

Synonyms

IPDI; 3-isocyanatomethyl-3,5,5-trimethylcyclohexylisocyanate; isophorone diamine diisocyanate.

SECTION II - HAZARDOUS INGREDIENTS AND IDENTITY INFORMATION

| Hazardous Components (specific identity) | OSHA Exposure Criteria | NIOSH Exposure Criteria | Immediately Dangerous to Life and Health (IDLH) | ACGIH Exposure Criteria |
|--|---|--|---|---|
| Isophorone diisocyanate 1 ppm = 9.24 mg/m³ | PEL: Not Established STEL: Not Established | REL (skin): 0.005 ppm 0.045 mg/m³ STEL: 0.02 ppm 0.18 mg/m³ | Not Determined | TLV (skin): 0.005 ppm 0.045 mg/m³ STEL: Not Established |

SECTION III - PHYSICAL AND CHEMICAL CHARACTERISTICS

| | |
|--|--|
| Boiling Point 316°F (158°C) | Specific Gravity (H ₂ O = 1) 1.06 |
| Vapor Pressure (mm Hg) 0.0003 at 68°F (20°C) | Molecular Weight 222.3 |
| Saturated Vapor Density (Air = 1.2 kg/m ³) Not Found | Melting Point -74°F (-60°C) |

Solubility

Decomposes in water; soluble in ethers, esters, ketones, and aliphatic and aromatic hydrocarbons.

Appearance and Odor

Clear, colorless, to slightly yellow liquid with a sharp, pungent odor.

SECTION IV - FIRE AND EXPLOSION HAZARD DATA

| | |
|--|--|
| Flash Point (method used) 311°F (155°C) closed cup | Explosive Limits in Air % by Volume LEL: Not Determined UEL: Not Determined |
| NFPA Classification Class IIIB Combustible Liquid | Autoignition Temperature Not Determined |

Extinguishing Media

Dry chemical, water spray, regular foam, or fog.

Special Fire Fighting Procedures

Wear full protective clothing and self-contained breathing apparatus (SCBA). Approach fire from upwind position. Remove containers from fire if it can be done without risk. Use a water spray to keep fire-exposed containers cool. Poisonous gases are produced in fire. Avoid smoke and contain runoff. Do not allow water from control measures to enter sewers or waterways.

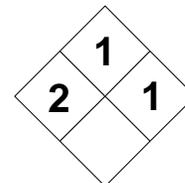

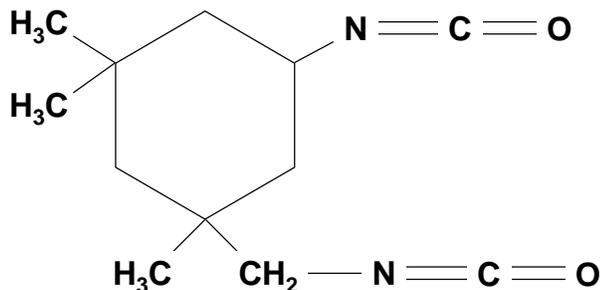

Unusual Fire and Explosion Hazards

Combustible when exposed to heat and flame. Containers may explode in fire. Stay clear of ends of tanks. Fight fire from maximum distance, if possible.

| SECTION V - REACTIVITY DATA | | | | |
|--|--|---|--------------------------------|--|
| Stability | | Conditions to Avoid Isophorone diisocyanate is normally stable at room temperature and pressure. Avoid contact with heat and incompatible materials. | | |
| Stable X | Unstable | Incompatibility (<i>materials to avoid</i>) Reacts with water (forms carbon dioxide), alcohols, phenols, amines, mercaptans, amides, urethane, ureas, and organo-metallic compounds (those containing aluminum, copper, or their alloys). | | |
| Hazardous Polymerization | | Conditions to Avoid Under normal conditions of temperature and pressure, hazardous polymerization of isophorone diisocyanate is not expected to occur. | | |
| May Occur | Will Not Occur X | Hazardous Decomposition or By-products When heated to decomposition, isophorone diisocyanate can emit highly toxic/poisonous fumes including fumes of carbon dioxide, toxic nitrogen oxides, and cyanide compounds. | | |
| SECTION VI - HEALTH HAZARD DATA | | | | |
| Primary Route(s) of Entry: | | Inhalation? X | Absorption (skin)? X | Ingestion? X |
| Health Hazards INHALATION: Irritation of the eyes, nose, throat, and respiratory tract with coughing, a choking sensation, deep chest pain or soreness, chest constriction and pain, severe bronchospasm, and pulmonary edema (fluid in the lungs). Asthmatic bronchitis can also occur. ABSORPTION: Skin contact may cause redness, swelling, painful blistering, and possible dermatitis. If the liquid contacts the eyes, there can be the development of conjunctivitis with severe inflammation of the eyelids. INGESTION: Unspecified gastrointestinal effects. | | | | |
| Carcinogenicity Unknown Human Unknown Animal | NTP Listed? No | IARC Cancer Review Group? No | OSHA Regulated? No | Target Organs? Respiratory system, eyes, skin. |
| Medical Conditions Generally Aggravated by Exposure Respiratory system problems or skin diseases may be aggravated by exposure. | | | | |
| Emergency and First-aid Procedures <u>Eye contact:</u> Flush immediately with water for 15 minutes (minimum); seek medical attention. <u>Skin contact:</u> Remove all contaminated clothing. Immediately wash area with large amounts of soap and water. For red or blistered skin, seek medical assistance. For <u>inhalation:</u> Remove the person from exposure. Provide respiratory assistance and CPR. Transfer to medical facility. Observe for 48 hours for lung effects. If <u>swallowed:</u> Contact poison control center. Unless advised otherwise, give conscious person 1 to 2 glasses of water to dilute. Do NOT induce vomiting (chemical is a severe irritant). | | | | |
| SECTION VII - PRECAUTIONS FOR SAFE HANDLING AND USE | | | | |
| Steps to be Taken in Case Material is Released or Spilled Absorb liquid solutions in vermiculite or similar material and place in sealed containers. Ventilate area of spill or leak. Remove all ignition sources. Restrict those not involved in cleanup from entering area. | | | | |
| Preferred Waste Disposal Method Mix in combustible solvent, burn in a chemical incinerator equipped with an afterburner and scrubber. | | | | |
| Precautions to be Taken in Handling and Storage Store in tightly closed containers in cool, dry, well-ventilated area away from heat, sparks, or flames. Sources of ignition are prohibited where isophorone diisocyanate is used, handled, or stored. | | | | |
| Other Precautions and Warnings Keep away from water or moisture. Do NOT reseal a container if contamination is suspected. Package for disposal or reclamation. Do NOT store in aluminum or copper containers. Protect from damage. | | | | |
| SECTION VIII - CONTROL MEASURES AND PERSONAL PROTECTIVE EQUIPMENT | | | | |
| Respiratory Protection (<i>specify type</i>) The NIOSH REL is low and difficult to monitor. For any exposure level, use an MSHA/NIOSH-approved supplied-air respirator with full facepiece, hood, or helmet in continuous flow mode, or use a self-contained breathing apparatus (SCBA) in continuous flow mode. | | | | |
| Ventilation Local exhaust or general mechanical systems recommended. | | | | |
| Protective Gloves Rubber, Polyvinyl Chloride (PVC) | Eye Protection Chemical Goggles or Face Mask | Other Protective Clothing Protective Apron or Clothing | | |
| Work/Hygiene Practices Always wash hands thoroughly after using chemical; never bring food, drink, or smoking materials into vicinity of chemicals. | | | | |

ISOPHORONE DIISOCYANATEC₁₂H₁₈N₂O₂

CAS: 4098-71-9

**IDENTIFICATION AND TYPICAL USES**

Isophorone diisocyanate appears as a clear, colorless to slightly yellow liquid with a sharp, pungent odor. It is used in the production of high-quality coatings, polyurethane paints, and varnishes that are resistant to light discoloration, abrasion, chemicals, chalking, and weathering. It is also used as an elastomer in casting compounds, mastics, and flexible tile coatings.

RISK ASSESSMENT: HEALTH**General Assessment**

Isophorone diisocyanate is an extremely toxic and poisonous substance. It can enter the body through *inhalation*, *absorption*, and by *ingestion*. It will also cause adverse health effects on contact with the skin or eyes. There is no information on its carcinogenic, teratogenic, or mutagenic capabilities in humans or animals.

Inhalation of isophorone diisocyanate vapors can be highly irritating to the eyes, nose, throat, and mucosa of the respiratory tract. Symptoms of exposure include wheezing, cough, deep chest pain, dyspnea, sweating, difficulty in breathing, severe bronchospasm, and possible life-threatening pulmonary edema (fluid in the lungs). Development of pulmonary edema may be delayed up to 48 hours thereby creating a false sense of security with regard to health exposure risk. In severe cases, there may be some restriction of air movement and eventual respiratory failure (due to edema). Prolonged contact can lead to chronic bronchitis, asthma-like symptoms, and allergic pulmonary sensitization. Isophorone diisocyanate is a cholinesterase inhibitor.

Skin contact causes irritation and painful burning with skin blisters and dermatitis on prolonged contact. If the liquid should contact the eye directly, there may

be irritation, inflammation of the eyelids and surrounding tissues, conjunctivitis, and possible damage to the cornea and subsequent visual impairment.

☠ Acute Health Effects

The following acute (short-term) health effects may occur immediately or shortly after exposure to isophorone diisocyanate:

Skin: Possible irritation with painful burning and blistering.

Eye: Moderate to severe irritation. There can be inflammation, irritation of the eyelids, and conjunctivitis.

Lung: Irritation of the nose, throat, and lungs following exposure. There can be a delayed but dangerous buildup of fluid in the lungs (pulmonary edema), which is a medical emergency.

☠ Chronic Health Effects

The following chronic (long-term) health effects may occur at some time after exposure to isophorone diisocyanate and can last for months or even years:

Cancer Hazards: There are insufficient data in the references on the carcinogenic or mutagenic properties of isophorone diisocyanate.

Reproductive Hazard: According to the data presented in the references, isophorone diisocyanate has not been adequately tested for its ability to adversely affect reproduction in test animals.

Other Chronic Effects: Long-term exposure to isophorone diisocyanate may lead to allergic sensitization of the respiratory system with initial symptoms of night coughs and difficulty breathing and possible

progression to asthmatic bronchitis. Dermal sensitization is also possible with rash and inflammation.

☉ **Recommended Risk-Reduction Measures**

Personnel should avoid direct contact with isophorone diisocyanate. If a less toxic chemical cannot be substituted for a hazardous substance, then *engineering controls* are the most effective method of reducing exposures. The best protection is to enclose operations and/or provide local exhaust ventilation at the site of chemical release. While not always operationally feasible, isolating operations can also reduce exposure. Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around isophorone diisocyanate. The NIOSH REL for this chemical is extremely low (0.005 ppm) and difficult to monitor reliably under most operating or emergency conditions. A supplied-air respirator with a full facepiece operated in positive pressure mode or an MSHA/NIOSH-approved self-contained breathing apparatus (SCBA) with full facepiece operated pressure demand or other positive pressure mode are the recommended respiratory protection methods of choice. In either case, if a full facepiece is not available, then chemical splash goggles should be worn to protect the eyes. Whenever a chemical splash hazard exists, a face shield and a protective apron should be worn. To prevent hand and skin exposures, impervious gloves should be used. Rubber and polyvinyl chloride materials should provide suitable protection. Glove manufacturers should be contacted and permeation studies obtained *before* final glove selections are made.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with isophorone diisocyanate.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where isophorone diisocyanate is used or stored.

If symptoms develop or overexposure is suspected, the following medical tests are recommended:

- ☑ Lung function tests.
- ☑ Consider chest X-ray following acute overexposure (may be negative if taken immediately after exposure due to delayed onset of pulmonary edema).
- ☑ Monitor arterial blood gases.

Also, since smoking can cause heart disease, emphysema, and other lung diseases, smokers exposed to isophorone diisocyanate may experience symptoms more quickly than non-smokers under the same conditions of exposure. Prudent risk management requires proper consideration of *all* possible exposure factors when evaluating workplace health hazard risk.

Other methods to reduce exposure include:

- ☑ Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not used, respiratory protection should be mandatory.
- ☑ Where possible, automatically transfer isophorone diisocyanate from drums or other storage containers to process containers.
- ☑ Always ensure that proper protective clothing is worn when using chemical substances and that personnel are trained on its use and care.
- ☑ Wash thoroughly immediately after exposure to isophorone diisocyanate and at the end of the work shift or before eating, drinking, or smoking.
- ☑ Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of isophorone diisocyanate should be communicated to all exposed and potentially exposed workers.

RISK ASSESSMENT: ENVIRONMENT

General Assessment

The environment is at risk of exposure during the transportation, storage, disposal, or destruction of isophorone diisocyanate. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance. Accidental spills, large or small, can result in fire, explosion, and possible contamination of the surrounding environmental mediums (water, soil, and air).

Isophorone diisocyanate is considered a Class IIIB combustible liquid (per OSHA 29 CFR 1910.106). It can react vigorously with oxidizing agents, water, alcohols, strong bases, amines, carboxylic acids, and organo-metallic catalysts. Pressure may build in closed containers. These characteristics require special consideration during any emergency situation involving a leak or spill of isophorone diisocyanate.

Isophorone diisocyanate may enter the environment primarily during the disposal of wastes from the chlorinated hydrocarbon industry.

☠ *Acute Ecological Effects*

Acute (short-term) toxic effects may include the death of animals, birds, or fish and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to isophorone diisocyanate.

Insufficient data are available to evaluate or predict the short-term effects of isophorone diisocyanate exposure to aquatic life, plants, birds, or land animals.

☀ *Chronic Ecological Effects*

Chronic (long-term) toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals.

Insufficient data are available to evaluate or predict the long-term effects of isophorone diisocyanate to aquatic life, plants, birds, or terrestrial animals.

💧 *Water Solubility*

Isophorone diisocyanate will sink and decompose in water to form its corrosive and toxic diamine and carbon dioxide. It is, therefore, only slightly soluble in the aquatic environment. Concentrations of less than 1 milligram will mix with a liter of water.

⌚ *Persistence in the Environment*

Isophorone diisocyanate is non-persistent in the aquatic environment, with a half-life of less than 2 days. The half-life of a pollutant is the amount of time it takes for one half of the chemical to be degraded.

🐟 *Bioaccumulation in Aquatic Organisms*

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans.

The concentration of isophorone diisocyanate found in fish tissues is expected to be much lower than the average concentration of isophorone diisocyanate in the water from which the fish was taken.

🛡️ *Recommended Risk-Reduction Measures*

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in a leak or spill to the environment. The correct use of labeling on all containers, trucks, and rail cars will enable

emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of isophorone diisocyanate should be segregated from incompatible chemicals to minimize the risk of cross-contamination or contact. Storage buildings or facilities should be equipped with proper fire protection equipment (sprinklers/extinguishers, alarms).

If a spill or leak to the environment has occurred, fire department, emergency response and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those trained in proper spill containment procedures using non-sparking tools. Contaminated soils should be removed for incineration and replaced with clean soil. If isophorone diisocyanate should contact the water table, aquifer, or navigable waterway, time is of the essence. Even though it is only slightly soluble in the aquatic environment, it will slowly react in water and, therefore, total containment and remediation may not be possible. When such spills occur, the local and/or state emergency response authorities must be notified. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of isophorone diisocyanate. The proper disposal method for isophorone diisocyanate is to burn it in a chemical incinerator equipped with an afterburner and an air scrubber.

If isophorone diisocyanate are spilled or leaked, the following specific response steps are recommended:

- ☑ Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened for normal work.
- ☑ Remove ignition sources and ventilate area.
- ☑ If liquid is spilled, absorb in vermiculite, dry sand, earth, or similar material and deposit in sealed containers. Use non-sparking tools.
- ☑ It may be necessary to dispose of isophorone diisocyanate as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving isophorone diisocyanate can present a significant threat to business op-

Risk Management for Hazardous Chemicals

erations. The loss or damage of equipment or facilities can significantly affect fiscal viability. Lawsuits that may result from personnel injury/death, public exposures, and/or environmental contamination will also require a serious expenditure of resources. Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business.

Recommended Risk-Reduction Measures

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures for responding to hazardous chemical incidents. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

| Health Hazards INHALATION: Symptoms include lachrymation, irritation of the throat and upper respiratory tract, general anesthesia, headache, burning cough, respiratory stimulation, nausea or vomiting, liver, kidney, or pulmonary changes (edema), and coma (especially if vapors are heated). ABSORPTION: Will pass through intact skin to cause toxic systemic effects as with inhalation. INGESTION: Same symptoms as inhalation, only more severe. May also cause CNS depression with excitement, nausea, vomiting, drowsiness, coma, respiratory or kidney failure, and death. | | | | |
| Carcinogenicity Unknown Human Unknown Animal | NTP Listed? No | IARC Cancer Review Group? No | OSHA Regulated? No | Target Organs? Resp. system, eyes, skin, CNS, blood, kidneys. |
| Medical Conditions Generally Aggravated by Exposure Any liver, kidney, cardiovascular, or nervous system disorders may be affected. | | | | |
| Emergency and First-aid Procedures <u>Eye contact:</u> Flush immediately with water for 15 minutes (minimum); seek medical attention. <u>Skin contact:</u> Remove all contaminated clothing. Immediately wash area with large amounts of soap and water. Seek medical assistance. For <u>inhalation:</u> Remove the person from exposure. Provide respiratory assistance and CPR, if required. Transfer to medical facility. Observe for 48 hours for lung effects (pulmonary edema). If <u>swallowed:</u> Seek medical attention immediately or contact poison control center. Unless told otherwise, give a conscious victim 1-2 glasses of water. Do NOT induce vomiting. | | | | |
| SECTION VII - PRECAUTIONS FOR SAFE HANDLING AND USE | | | | |
| Steps to be Taken in Case Material is Released or Spilled Absorb large spills in vermiculite or similar material and deposit in sealed containers. Ventilate area of spill or leak. Restrict those not involved in cleanup from entering area. Remove all sources of ignition. | | | | |
| Preferred Waste Disposal Method Burn in chemical incinerator equipped with an afterburner and scrubber. | | | | |
| Precautions to be Taken in Handling and Storage Store to avoid contact with incompatible materials in tightly closed containers in cool, well-ventilated area away from heat and flame. Use only non-sparking tools to open and close containers. | | | | |
| Other Precautions and Warnings Sources of ignition are prohibited where 2-isopropoxyethanol is used, handled, or stored. Heat may cause containers to build up pressure and explode. Containers and equipment must be grounded and bonded, especially during liquid transfer. Protect containers from physical damage. | | | | |
| SECTION VIII - CONTROL MEASURES AND PERSONAL PROTECTIVE EQUIPMENT | | | | |
| Respiratory Protection (<i>specify type</i>) For low exposures, use a chemical cartridge respirator. Otherwise, use an MSHA/NIOSH-approved supplied-air respirator with full facepiece, hood, or helmet in continuous flow mode, or use a self-contained breathing apparatus (SCBA) operated in pressure demand or other positive pressure mode. | | | | |
| Ventilation Local exhaust or general mechanical systems recommended. | | | | |
| Protective Gloves Impervious Material | Eye Protection Chemical Goggles or Face Mask | Other Protective Clothing Protective Apron | | |
| Work/Hygiene Practices Always wash hands thoroughly after using chemical; never bring food, drink, or smoking materials into vicinity of chemicals. | | | | |

2-ISOPROPOXYETHANOL

CAS: 109-59-1

IDENTIFICATION AND TYPICAL USES

2-Isopropoxyethanol is a clear, colorless, mobile liquid with a mild, ethereal odor. It is used as a component of lacquers and other coatings and as a solvent for resins, dyes, and textiles.

RISK ASSESSMENT: HEALTH

General Assessment

2-Isopropoxyethanol is mildly toxic to humans by *ingestion* and *inhalation*. It will also pass through unbroken skin (*absorption*) to cause toxic systemic effects equal or greater than that caused by inhalation or ingestion. This is especially true if absorption occurs in tandem with some other exposure, such as inhalation. It is a severe central nervous system depressant. There are no reports in the references to indicate that exposure causes cancer, reproductive effects, or mutations in humans or animals.

Toxic systemic effects by all routes of exposure can include hemolytic anemia, digestive problems, dizziness, respiratory distress, and renal dysfunction. Symptoms of exposure can include abdominal pain, dehydration, nausea, vomiting, general weakness and muscle tenderness, acidosis and resultant hyperpnea (rapid, deep respiration), and pulmonary edema (fluid in the lungs). The development of pulmonary edema and associated symptoms may be delayed up to 48 hours, thereby creating a false sense of security with regard to health exposure risk. CNS depression may cause excitement or exhilaration, drunkenness and stupor, ataxia, dizziness, coma, and possible convulsions. Renal effects include lower back pain, excessive protein in urine (albuminuria), excessive blood in urine (hematuria), reduction in urine secretion (oliguria), and kidney failure leading to water retention in the extremities (peripheral edema). If death occurs, it is usually due to respiratory arrest or cardiovascular collapse.

Skin and eye contact may produce mild to moderate irritation on contact and may cause an allergic reaction and rash. It will pass through unbroken skin to cause many of the toxic systemic effects noted for inhalation.

☠ *Acute Health Effects*

The following acute (short-term) health effects may occur immediately or shortly after exposure to 2-isopropoxyethanol:

Skin: Some irritation at site of contact. Allergic rash may develop. Absorption is likely.

Eye: Mild to moderate irritation.

Lung: Nose and throat irritation. Produces intoxicating effects and may cause lung effects, such as pulmonary edema.

CNS: Stimulation and depression with symptoms of dizziness, headache, lightheadedness, nausea, vomiting, and coma.

☘ *Chronic Health Effects*

The following chronic (long-term) health effects may occur at some time after exposure to 2-isopropoxyethanol and can last for months or even years:

Cancer Hazards: According to information presented in the references, 2-isopropoxyethanol has not been adequately tested for its ability to cause cancer in animals.

Reproductive Hazard: According to information presented in the references, 2-isopropoxyethanol has not been adequately tested for its ability to adversely affect reproduction in test animals.

Other Chronic Effects: Repeated exposures may cause blood effects such as hemolytic anemia (destruction of red blood cells). Skin rash and/or der-

matitis may develop following prolonged or repeated contact.

🔊 **Recommended Risk-Reduction Measures**

Personnel should avoid direct contact with 2-isopropoxyethanol. This chemical is toxic to humans by all exposure routes (inhalation, ingestion, and dermal absorption). If a less toxic chemical cannot be substituted for a hazardous substance, then *engineering controls* are the most effective method of reducing exposures. The best protection is to enclose operations and/or provide local exhaust ventilation at the site of chemical release. While not always operationally feasible, isolating operations can also reduce exposure. Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around 2-isopropoxyethanol. Chemical cartridge respirators may provide adequate protection up to the PEL. However, the best protection is obtained using a supplied-air respirator with full facepiece operated in continuous flow mode, or a self-contained breathing apparatus (SCBA) with full facepiece operated in pressure demand. If a full facepiece is not available, then chemical goggles should be worn to protect the eyes. Whenever a chemical splash hazard exists, a face shield and a protective apron should be worn. To prevent hand and skin exposures, impervious gloves should be used. Glove manufacturers should be contacted and permeation studies obtained *before* final glove selections have been made.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with or around 2-isopropoxyethanol.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where 2-isopropoxyethanol is used or stored.

If symptoms develop or overexposure is suspected, the following tests are recommended:

- ☑ Kidney function tests.
- ☑ Urine oxalate level. Urinalysis may show low specific gravity, proteinuria, pyuria, cylinduria, hematuria, calcium oxalate, and hippuric crystals.
- ☑ Lung function tests.
- ☑ Consider chest X-ray following acute overexposure (may be negative if taken immediately after

exposure due to delayed onset of pulmonary edema).

Any evaluation should include a careful history of past and present symptoms with an examination. Medical tests that simply look for existing damage are not a substitute for controlling exposures. Sodium bicarbonate may be used intravenously to treat acidosis. Ethanol may be used in antedotal treatment. However, blood glucose levels must be monitored for hypoglycemia. Also, since smoking can cause heart disease, lung cancer, emphysema, and other respiratory disorders, smokers exposed to 2-isopropoxyethanol may experience symptoms more rapidly or more pronounced than non-smokers under the same conditions of exposure. Prudent risk management requires proper consideration of *all* possible factors which may be causing the appearance of exposure symptoms in the workplace.

Other methods to reduce exposure include:

- ☑ Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not used, respiratory protection should be mandatory.
- ☑ Where possible, automatically transfer liquid 2-isopropoxyethanol from storage drums to process containers. Electrically ground and bond all containers and equipment, especially during transfer operations.
- ☑ Always ensure that proper protective clothing is worn when using chemical substances and that personnel are trained in its use and care.
- ☑ Wash thoroughly immediately after exposure to 2-isopropoxyethanol and at the end of the work shift or before eating, drinking, or smoking.
- ☑ Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards associated with 2-isopropoxyethanol should be communicated to all potentially exposed workers.
- ☑ Eye wash stations should be provided in the immediate work area for emergency use. If there is a possibility of skin exposure to this chemical, then emergency shower facilities should also be provided in the immediate work area.
- ☑ Personnel should never wear contaminated clothing home (family members can be exposed). Clothing should be laundered only by personnel

who have been properly trained on hazards associated with exposure to 2-isopropoxyethanol.

RISK ASSESSMENT: ENVIRONMENT

General Assessment

The environment is at risk of exposure during transportation, storage, disposal, or destruction of 2-isopropoxyethanol. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance. Accidental spills, large or small, can result in fire, explosion, and possible contamination of the surrounding environmental mediums (water, soil, and air).

2-Isopropoxyethanol is considered a Class IC flammable liquid (per OSHA 29 CFR 1910.106). Its relatively low flash point and moderate boiling point present a serious fire and explosion hazard, especially in confined spaces. Its vapors are heavier than air and can travel for great distances to an ignition source to flashback and cause fire or explosion. These characteristics require extreme caution in handling, storage, transportation, and disposal. It is incompatible with many common peroxides and other oxidizers and contact can cause fire or explosion. Therefore, special consideration is required during any emergency situation involving a leak or spill of 2-isopropoxyethanol. Should 2-isopropoxyethanol ever come into contact with any incompatible substances during use, transportation, storage, or disposal, the formation of highly toxic and/or highly explosive commodities is extremely possible. The proper method for disposing of waste 2-isopropoxyethanol is to burn it in a chemical incinerator equipped with an afterburner and scrubber.

2-Isopropoxyethanol may enter the environment through industrial or municipal waste treatment plant discharges, agricultural runoff or disposal, or spills.

☠ Acute Ecological Effects

Acute (short-term) toxic effects may include the death of animals, birds, or fish and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to 2-isopropoxyethanol.

Insufficient data are available to evaluate or predict the short-term effects of 2-isopropoxyethanol exposure to aquatic life, plants, birds, or land animals.

☠* Chronic Ecological Effects

Chronic (long-term) toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after

(sometimes months or even years) first exposure(s) to toxic chemicals.

Insufficient data are available to evaluate or predict the long-term effects of 2-isopropoxyethanol exposure on aquatic life, birds, plants, or land animals.

💧 Water Solubility

2-Isopropoxyethanol is highly soluble in water. Concentrations of 1000 milligrams and more will mix with a liter of water.

⌚ Persistence in the Environment

2-Isopropoxyethanol is slightly persistent in water, with a half-life between 2 and 20 days. The half-life of a pollutant is the amount of time it takes for one half of the chemical to be degraded.

🐟 Bioaccumulation in Aquatic Organisms

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans.

No data are available on the bioaccumulation properties of 2-isopropoxyethanol.

🛡 Recommended Risk-Reduction Measures

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in a leak or spill to the environment. The correct use of DOT labeling (per the MSDS) on all containers, trucks, and rail cars will enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of 2-isopropoxyethanol should be segregated from incompatible chemicals to minimize the risk of cross-contamination or contact. Buildings designated for storage should be equipped with appropriate fire protection systems (alarms, sprinklers, emergency lighting, portable extinguishers).

If a spill or leak to the environment has occurred, fire department, emergency response and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those trained in proper spill containment procedures using non-sparking tools. Contaminated soils should be removed for incineration and replaced with clean soil. If 2-isopropoxyethanol should contact the water table, aquifer, or navigable waterway, cleanup should be

started immediately. It is highly soluble in water and total remediation may not be possible. The local and/or state emergency response authorities must be notified. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of 2-isopropoxyethanol. If this chemical is spilled or leaked, the following specific steps are recommended:

- ☑ Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened for normal work.
- ☑ Remove all ignition sources; ventilate area of leak.
- ☑ Absorb liquids in vermiculite, dry sand, earth, or similar material and deposit in sealed containers using non-sparking tools.
- ☑ It may be necessary to dispose of this compound as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving 2-isopropoxyethanol can present a significant threat to business operations. The loss or damage of equipment or facilities can significantly affect fiscal viability. Lawsuits that may result from personnel injury/death, public exposures, and/or environmental contamination will also require a serious expenditure of resources.

Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business.

🔧 *Recommended Risk-Reduction Measures*

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures dealing with safety or emergency response. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

ISOPROPYL ACETATE

CAS: 108-21-4

**IDENTIFICATION AND TYPICAL USES**

Isopropyl acetate is a colorless liquid with a characteristic fruity odor. It is used as a solvent for nitrocellulose, oils, fats, and resin gums; in the manufacture of thinners, sealants, paints, topcoat lacquers, and printing inks; in organic synthesis; in perfumery; and as a flavoring agent.

RISK ASSESSMENT: HEALTH***General Assessment***

Isopropyl acetate is mildly toxic by *inhalation* and *ingestion*. Skin contact can produce localized effects but dermal absorption has not been reported. There are no reports of any carcinogenic, teratogenic, or mutagenic effects in humans or animals following exposure to isopropyl acetate.

Inhalation of isopropyl acetate vapors can cause irritation to the eyes, nose, throat, and respiratory tract with nausea, vomiting, cough, shortness of breath, and unconsciousness. Depending upon the concentration and duration of the exposure, there can also be varying degrees of central nervous system depression. Symptoms may include headaches, dizziness, general weakness and fatigue, loss of consciousness, difficulty in breathing, increased or rapid pulse rate, unconsciousness, and death. High or chronic exposure can lead to liver damage.

Skin contact results in the removal of the skin's natural protective oily layer on its surface with subsequent drying, cracking, and possible secondary infections and dermatitis. Eye contact can cause irritation and the possibility for adverse effects to vision.

Ingestion of isopropyl acetate may cause irritation of the mouth, esophagus, stomach, and digestive tract with nausea and vomiting. There can also be gastro-

intestinal hemorrhage, liver damage, and cardiac failure.

☠ *Acute Health Effects*

The following acute (short-term) health effects may occur immediately or shortly after exposure to isopropyl acetate:

Skin: Mild to moderate irritation. Will remove the skin's protective oily layer causing drying, cracking, secondary infection, and dermatitis.

Eye: Irritation and possible inflammation.

Lung: Irritation of the eyes, nose, throat, and lungs (especially the mucus membranes). May cause olfactory changes and pulmonary effects.

CNS: High concentrations can depress the central nervous system leading to narcoses and possible loss of consciousness.

☘ *Chronic Health Effects*

The following chronic (long-term) health effects may occur at some time after exposure to isopropyl acetate and can last for months or even years:

Cancer Hazards: According to the references, isopropyl acetate has not been adequately tested for its ability to cause cancer in test animals.

Reproduction: According to the references, isopropyl acetate has not been adequately tested for its ability to adversely affect reproduction in test animals.

Other Chronic Effects: Repeated or prolonged skin contact may cause the development of contact dermatitis with rash, redness, and inflammation of the affected surface area. Liver damage may also occur.

🕒 **Recommended Risk-Reduction Measures**

Personnel should avoid direct contact with isopropyl acetate. The best risk reduction measure is to use a less toxic chemical as a substitute for isopropyl acetate. If this is not possible or practical, then *engineering controls* are the most effective method of reducing exposures. The best protection is to enclose operations and/or provide local exhaust ventilation at the site of chemical release. While not always operationally feasible, isolating operations can also reduce exposure risks to other personnel. Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around isopropyl acetate. For exposures over 250 ppm (8 hours), a chemical respirator with an organic vapor cartridge should be used. For higher exposures, a self-contained breathing apparatus (SCBA) with full facepiece operated in pressure demand mode or a supplied-air respirator with full facepiece operated in positive pressure or other continuous flow mode are the recommended respiratory protection methods of choice. If a full facepiece is not available, then chemical goggles should be worn to protect the eyes. Whenever a chemical splash hazard exists, a face shield and a protective apron should be worn. To prevent hand and skin exposures, impervious gloves should be used. Caution is warranted in glove selection since isopropyl acetate will attack many plastic formulations and rubber materials. Glove manufacturers should always be contacted to obtain permeation studies *before* gloves are selected.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with isopropyl acetate.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where isopropyl acetate is used or stored.

If symptoms develop or overexposure is suspected, the following medical tests are recommended:

- ☑ Lung function tests.
- ☑ Liver and kidney function tests.
- ☑ Skin testing with dilute isopropyl acetate to help diagnose allergy (performed by a qualified allergist under controlled conditions).

Any medical evaluation should include a careful history of past and present symptoms with an examination. Medical tests that look for existing damage are not a substitute for controlling exposures. Also, since smoking can cause heart disease, emphysema, and other respiratory disorders, smokers exposed to isopropyl acetate may experience symptoms more quickly than non-smokers under the same conditions of exposure. Prudent risk management requires proper consideration of *all* factors which may be causing the appearance of exposure symptoms in the workplace.

Other methods to reduce exposure include:

- ☑ Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not used, respiratory protection should be mandatory.
- ☑ Always ensure that proper protective clothing is worn when using chemical substances.
- ☑ Wash thoroughly immediately after exposure to isopropyl acetate and at the end of the work shift or before eating, drinking, or smoking.
- ☑ Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of isopropyl acetate should be communicated to all exposed workers.
- ☑ Never eat, drink, or smoke in areas where isopropyl acetate is used, handled or stored.
- ☑ Never wear contaminated work clothing home where family members can be exposed. Clothing should be laundered only by personnel who have been briefed on the hazards of isopropyl acetate.

RISK ASSESSMENT: ENVIRONMENT

General Assessment

The environment is at risk of exposure during transportation, storage, disposal, or destruction of isopropyl acetate. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance.

Accidental spills, large or small, can result in fire, explosion, and possible contamination of the surrounding environmental mediums (water, soil, and air). Isopropyl acetate is considered a Class IB flammable liquid (according to OSHA 29 CFR 1910.106). Its moderately low flash point presents a serious fire and explosion hazard concern. Also, because it is incompatible with a number of common materials, espe-

Risk Management for Hazardous Chemicals

cially strong oxidizers and acids, contact can result in violent and explosive reactions. It can also form explosive mixtures in air and can ignite on contact with heat, fire, or sparks. These characteristics require special consideration during any emergency situation involving a leak or spill of isopropyl acetate. The proper disposal method for isopropyl acetate is to burn it in a chemical incinerator equipped with an afterburner and air scrubber. Isopropyl acetate can enter the environment through unchecked industrial discharges and through accidental spills.

☠ *Acute Ecological Effects*

Acute (short-term) toxic effects may include the death of animals, birds, or fish, and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to isopropyl acetate.

Insufficient data are available to evaluate or predict the short-term effects of isopropyl acetate to aquatic life, plants, birds, or terrestrial animals.

🕒 *Chronic Ecological Effects*

Chronic toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals.

Insufficient data are available to evaluate or predict the long-term effects of isopropyl acetate to aquatic life, plants, birds, or land animals.

💧 *Water Solubility*

Isopropyl acetate is only slightly soluble in water. Concentrations of 1 to 100 milligrams may mix with a liter of water.

🕒 *Persistence in the Environment*

Isopropyl acetate is highly persistent in water, with a half-life greater than 200 days. The half-life of a pollutant is the amount of time it takes for one-half of the chemical to be degraded.

There is insufficient information in the references to evaluate or predict the total percentages of isopropyl acetate that will eventually end up in the various environmental mediums (air, water, and soil).

🐟 *Bioaccumulation in Aquatic Organisms*

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat con-

taminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans.

Insufficient data are available to evaluate or predict the accumulation rate of isopropyl acetate in the edible tissues of fish.

🛡️ *Recommended Risk-Reduction Measures*

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in a leak or spill to the environment. The correct use of DOT labeling (per the MSDS) on all containers, trucks, and rail cars will enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of isopropyl acetate should be segregated from incompatible chemicals to minimize the risk of cross-contamination or contact. Buildings designated for storage should be equipped with appropriate fire protection systems (alarms, sprinklers, emergency lighting, portable extinguishers).

If a spill or leak to the environment has occurred, fire department, emergency response, and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those trained in proper spill containment procedures using non-sparking tools. Contaminated soils should be removed for incineration and replaced with clean soil. If isopropyl acetate should contact the water table, aquifer, or navigable waterway, time is of the essence. It is only slightly soluble in water and, therefore, total containment and remediation may be possible. When such spills occur, the local and/or state emergency response authorities must be notified. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of isopropyl acetate. If isopropyl acetate is spilled or leaked, the following specific steps are recommended:

- ☑ Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened for normal work.
- ☑ Ventilate area and remove all ignition sources.
- ☑ Absorb liquids in vermiculite, dry sand, earth, or a similar material and deposit in sealed containers. Use non-sparking tools!
- ☑ It may be necessary to dispose of isopropyl acetate as a hazardous waste. The responsible state agency or the regional office of the federal Envi-

Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving isopropyl acetate can present a moderate threat to business operations. The loss or damage of equipment or facilities can significantly affect fiscal viability. Lawsuits that may result from personnel injury/death, public exposures, and/or environmental contamination will also require a serious expenditure of resources. Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business.

Recommended Risk-Reduction Measures

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures or policies intended to manage the use of chemicals in the workplace. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

SECTION I - GENERAL INFORMATION

| | | |
|---|---|--|
| Characterization Alcohol | RCRA Number D001 | EPA Class Characteristic (I) Waste |
| DOT Proper Shipping Name Isopropanol or Isopropyl Alcohol | Chemical Abstract Service (CAS) Number 67-63-0 | |
| DOT Hazard Class and Label Requirements Flammable Liquid | DOT Emergency Guide Code 26 | |
| DOT Identification Number UN 1219 | Chemical Formula (CH₃)₂CHOH | |

Synonyms

IPA; isopropanol; dimethyl carbinol; 2-propanol; sec-propyl alcohol; rubbing alcohol.

SECTION II - HAZARDOUS INGREDIENTS AND IDENTITY INFORMATION

| Hazardous Components (specific identity) | OSHA Exposure Criteria | NIOSH Exposure Criteria | Immediately Dangerous to Life and Health (IDLH) | ACGIH Exposure Criteria |
|--|---|--|---|--|
| Isopropyl alcohol (derivation: By treating propylene with sulfuric acid and then hydrolyzing, or by direct hydration of propylene using steam.) Commonly sold as Rubbing Alcohol at 70% 1 ppm = 2.5 mg/m³ | PEL (8-hour): 400 ppm 980 mg/m³ STEL: Not Established | REL (10-hour): 400 ppm 980 mg/m³ STEL: 500 ppm 1225 mg/m³ | 12,000 ppm | TLV: 400 ppm 983 mg/m³ STEL: 500 ppm 1230 mg/m³ |

SECTION III - PHYSICAL AND CHEMICAL CHARACTERISTICS

| | |
|--|--|
| Boiling Point 181°F (83°C) | Specific Gravity (H ₂ O = 1) 0.79 |
| Vapor Pressure (mm Hg) 33 at 68°F (20°C) | Molecular Weight 60.1 |
| Vapor Density (Air = 1) 2.07 | Melting Point -127°F (-88.3°C) |

Solubility

Miscible in water. Soluble in alcohol, ether, chloroform, and benzene. Insoluble in salt solutions.

Appearance and Odor

Colorless liquid with a slight odor of rubbing alcohol and bitter taste. Odor Threshold = 22 ppm.

SECTION IV - FIRE AND EXPLOSION HAZARD DATA

| | |
|--|---|
| Flash Point (method used) 53°F (12°C) closed cup | Explosive Limits in Air % by Volume LEL: 2.0% UEL: 12.7% at 200°F (93°C) |
| NFPA Classification Class IB Flammable Liquid | Autoignition Temperature 750°F (399°C) |

Extinguishing Media

Dry chemical, carbon dioxide, or alcohol-resistant foam, fog, or water spray.

Special Fire Fighting Procedures

Poisonous gases are produced in fire. Wear full protective clothing and self-contained breathing apparatus (SCBA). Continue to cool containers with water after fire is extinguished. Move containers from fire area if it can be done without risk. For large fires, use unmanned hose apparatus, if possible. Evacuate non-essential personnel one-half mile radius if fire. Consider down-wind conditions.

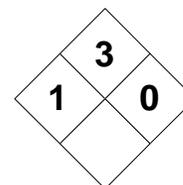

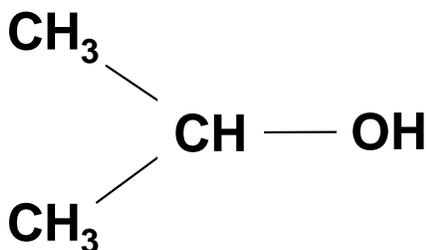

Unusual Fire and Explosion Hazards

Vapors are heavier than air and may travel a distances to ignition source to flashback. Vapors may explode if ignited in an enclosed area. Evacuate area if rising sound is heard from venting device.

| SECTION V - REACTIVITY DATA | | | | |
|--|--|--|--|---|
| Stability | | Conditions to Avoid Isopropyl alcohol is stable under normal conditions of storage and operation. Avoid contact with incompatible materials. Keep away from heat, flame, and other ignition sources. | | |
| Stable X | Unstable | Incompatibility (<i>materials to avoid</i>) Reacts violently in contact with strong oxidizers, inorganic acids, aldehydes (especially acetaldehyde), and isocyanates. It ignites on contact with many metallic oxides. | | |
| Hazardous Polymerization | | Conditions to Avoid Under normal conditions of temperature and pressure, isopropyl alcohol is not expected to undergo hazardous polymerization. | | |
| May Occur | Will Not Occur X | Hazardous Decomposition or By-products When heated to decomposition, isopropyl alcohol emits acrid and irritating fumes including toxic oxides of carbon. | | |
| SECTION VI - HEALTH HAZARD DATA | | | | |
| Primary Route(s) of Entry: | | Inhalation? X | Absorption (skin)? | Ingestion? X |
| Health Hazards INHALATION: There may be slight irritation of the eyes, nose, and mucosa of the respiratory tract. Exposure can also cause stupor, fatigue, and sleepiness. Other effects include nausea, vomiting, flushing of skin, headaches, double vision, vertigo, weakness, sleepiness, olfactory changes (fatigue of sense of smell), pulmonary edema, and death. SKIN & EYES: As a solvent, causes skin dryness, cracking, and possible dermatitis. Eye contact can result in burning, stinging, tearing, corneal injury, and possible corneal burns. INGESTION: Sleep disorders, hallucinations, distorted perceptions, convulsions, ataxia and motor activity changes, renal and liver damage, cardiac failure, coma, headache, and death. | | | | |
| Carcinogenicity Unknown Human Questioned Animal | NTP Listed? No | IARC Cancer Review Group? Group 3 | OSHA Regulated? 29 CFR 1910.1000 Table Z-1 | Target Organs? Skin, eyes, respiratory system, CNS. |
| Medical Conditions Generally Aggravated by Exposure Chronic liver, kidney, and chronic respiratory diseases may be aggravated by exposure. | | | | |
| Emergency and First-aid Procedures Eye contact: Flush immediately with water for 15 minutes (minimum); seek medical attention. Skin contact: Remove all contaminated clothing. Immediately wash area with large amounts of soap and water. Seek medical assistance. For inhalation: Remove the person from exposure. Provide respiratory assistance and CPR. Transfer to medical facility. Observe for 48 hours for lung effects. If swallowed: Contact poison control center. Give 1-2 glasses of water or milk to dilute. Do NOT induce vomiting. Gastric lavage is preferred. Seek medical attention immediately. | | | | |
| SECTION VII - PRECAUTIONS FOR SAFE HANDLING AND USE | | | | |
| Steps to be Taken in Case Material is Released or Spilled Contain spills using absorbent material (vermiculite). Ventilate area of spill and remove ignition sources. Have extinguishing agent available in case of fire. Store in DOT-approved containers. | | | | |
| Preferred Waste Disposal Method Incineration in chemical incinerator equipped with scrubber and afterburner. | | | | |
| Precautions to be Taken in Handling and Storage Store in tightly closed containers in a cool, dark, well-ventilated area. Protect containers from physical damage. Keep heat, fire, and flame away. Outside building or underground storage is recommended. | | | | |
| Other Precautions and Warnings Ground and bond all metal containers. Avoid contact with skin and eyes. | | | | |
| SECTION VIII - CONTROL MEASURES AND PERSONAL PROTECTIVE EQUIPMENT | | | | |
| Respiratory Protection (<i>specify type</i>) For vapor exposures, use an organic vapor air-purifying respirator. Greater protection is obtained using a supplied-air respirator or a self-contained breathing apparatus (SCBA) with full facepiece operated in pressure demand or other positive pressure mode. | | | | |
| Ventilation Local exhaust or general mechanical systems recommended. | | | | |
| Protective Gloves Impervious Gloves | Eye Protection Chemical Goggles or Face Mask | Other Protective Clothing Impermeable Apron or Protective Suit | | |
| Work/Hygiene Practices Always wash hands thoroughly after using chemical; never bring food, drink, or smoking materials into vicinity of chemicals. | | | | |

ISOPROPYL ALCOHOL

CAS: 67-63-0

**IDENTIFICATION AND TYPICAL USES**

Isopropyl alcohol is a colorless or clear liquid with an odor of rubbing alcohol and a bitter taste. It is used in the manufacture of acetone and its derivatives and in the manufacture of glycerol and isopropyl acetate. It is also a strong and commonly used industrial solvent for cutting essential oils, other oils, alkaloids, gums, and resins. It is a latent solvent for cellulose derivatives and lacquers, a coatings solvent, a deicing agent for many liquid fuels, used in extraction processes, a dehydrating agent, a preservative, used in lotions, and as a denaturant.

RISK ASSESSMENT: HEALTH***General Assessment***

Isopropyl alcohol is primarily toxic to humans by *inhalation* and *ingestion*. Skin contact can cause adverse surface effects but dermal absorption has not been reported. Isopropyl alcohol is a questioned animal carcinogen (the IARC reports insufficient evidence) and its human carcinogenic potential is unknown. Mutation data have also been reported as have experimental teratogenic and reproductive effects.

Inhalation can cause irritation of the eyes, nose, throat, upper respiratory tract, and associated mucosa. There may also be depression of the central nervous system (CNS) with narcosis and associated symptoms, including headache, nervousness, flushing of the skin, double vision, vertigo, tremors, dizziness, fatigue and general weakness, nausea, somnolence, and narcosis with stupor, loss of consciousness, and death. Pulmonary edema and/or chemical pneumonia can also occur, most often as a result of aspiration of the fluid into the lungs. The symptoms of pulmonary edema

may be delayed up to 48 hours which can create a false sense of security with regard to health exposure risk.

Liquid contact with the eyes causes immediate burning and stinging with lachrymation and reflex closure of the lids. There may be severe, irreversible damage or injury to the cornea with possible conjunctivitis, depending upon the duration of exposure and concentration strength. Skin contact results in drying and cracking which can lead to secondary infections and dermatitis.

Ingestion of isopropyl alcohol can lead to symptoms of alcohol toxicity. These include nausea and vomiting, headache, flushing of the face, dizziness, decreased blood pressure, mental depression, hallucinations and distorted perceptions, dyspnea, respiratory depression, stupor, sleep disorders, ataxia, motor function changes, convulsions and tremors, coma, loss of body temperature, renal and liver damage, gastrointestinal damage, cardiac failure, unconsciousness, coma, and death. Kidney effects may include oliguria (reduction in urine secretion) or anuria (lack of urine secretion), nitrogen retention, and edema.

☠ *Acute Health Effects*

The following acute (short-term) health effects may occur immediately or shortly after exposure to isopropyl alcohol:

- Skin:** Causes dryness and cracking leading to dermatitis and possible infection with erythema.
- Eye:** Severe irritation with burning, stinging, and possible damage to the cornea.
- Lung:** Irritation of the eyes, nose, throat, and respiratory tract. Delayed pulmonary edema is also a possible effect, especially on aspiration of the liquid, which can be fatal.

CNS: High concentrations either through inhalation or ingestion can cause depression of the CNS with symptoms of sleepiness, stupor, inebriation, vertigo, loss of consciousness, and death.

☛ **Chronic Health Effects**

The following chronic (long-term) health effects may occur at some time after exposure to isopropyl alcohol and can last for months or even years:

Cancer Hazards: Isopropyl alcohol has been shown to cause cancer in limited experiments with test animals. However, more studies are required in this regard before any carcinogenic determinations can be made for animals or humans. Mutation data have been reported. Many scientists believe that such chemicals pose a cancer risk in the long-term.

Reproduction: According to the references, isopropyl alcohol has been shown to cause teratogenic and other adverse reproductive effects in animal experiments. It is not known whether or not it will have these effects in humans.

Other Chronic Effects: Very high or prolonged exposure may result in mucous membrane irritation, headache, and depression of the CNS with symptoms of somnolence and lack of concentration. Prolonged skin contact can cause drying, cracking, and dermatitis.

🕒 **Recommended Risk-Reduction Measures**

Personnel should avoid direct contact with isopropyl alcohol. The exact nature of its toxicity is not clearly understood in the references and its carcinogenic capability is considered suspect. The best risk reduction measure is to use a less toxic chemical as a substitute for a isopropyl alcohol. However, as one of the most commonly used industrial solvents, substitution may not be possible or operationally feasible. Therefore, *engineering controls* are the most effective methods of reducing exposures. An alternative method of protection is to enclose operations and/or provide local exhaust ventilation at the site of chemical release. While not always operationally feasible, isolating operations can also reduce exposure risk.

Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around isopropyl alcohol. For concentrations over the PEL (400 ppm), an air-purifying respirator with an organic vapor cartridge will suffice. For higher exposures, a supplied-air respirator with full facepiece operated in positive pressure mode, or a self-contained breathing apparatus (SCBA) with full facepiece and operated in pressure

demand mode are the recommended respiratory protection methods of choice. If a full facepiece is not available, then chemical goggles should be worn to protect the eyes. Whenever a chemical splash hazard exists, a face shield and a protective apron should be worn. To prevent hand and skin exposures, impervious gloves should be used. Glove manufacturers should be contacted and permeation studies obtained *before* final glove selections have been made.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with isopropyl alcohol.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where isopropyl alcohol is used or stored.

If symptoms develop or overexposure is suspected, the following medical tests are recommended:

- Evaluation of nervous system function with careful consideration of exposure history and special testing by a qualified neurologist.
- Complete blood count (CBC) and determination of isopropyl alcohol levels (or its metabolites).
- Urinalysis (check for acetone levels).
- Liver, kidney, and lung function tests.
- Consider chest X-ray following acute overexposure (may be negative if taken immediately after exposure due to delayed onset of pulmonary edema).
- Skin testing with dilute isopropyl alcohol to help diagnose allergy (performed by a qualified allergist).

Any medical evaluation should include a careful history of past and present symptoms with an examination. Medical tests that look for existing damage are not a substitute for controlling exposures. Also, since smoking can cause heart disease, lung cancer, emphysema, and other respiratory diseases, smokers exposed to isopropyl alcohol may experience symptoms more rapidly than non-smokers under the same conditions of exposure.

Other methods to reduce exposure include:

- Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not used, respiratory protection should be mandatory.

- ☑ Always ensure that proper protective clothing is worn when using chemical substances.
- ☑ Wash thoroughly immediately after exposure to isopropyl alcohol and at the end of the work shift or before eating, drinking, or smoking.
- ☑ Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of isopropyl alcohol should be communicated to all exposed workers.

RISK ASSESSMENT: ENVIRONMENT

General Assessment

The environment is at risk of exposure during transportation, storage, disposal, or destruction of isopropyl alcohol. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance. Accidental spills, large or small, can result in fire, explosion, and possible contamination of the surrounding environmental mediums (water, soil, and air).

Isopropyl alcohol is considered a Class IB flammable liquid (according to OSHA 29 CFR 1910.106). Its relatively low flash point presents a moderate fire and explosion hazard concern. Also, because it is incompatible with a number of common materials, especially strong oxidizers and many reducing materials, contact can result in violent and explosive reactions. It can also react explosively with many metallic oxides and can ignite on contact with heat, fire, or sparks. These characteristics require special consideration during any emergency situation involving a leak or spill of isopropyl alcohol. The proper destruction method is to burn it in an incinerator with an after-burner and scrubber.

Isopropyl alcohol can enter the environment through unchecked industrial discharges into effluents and through spills.

☠ *Acute Ecological Effects*

Acute (short-term) toxic effects may include the death of animals, birds, or fish, and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to isopropyl alcohol.

Insufficient data are available to evaluate or predict the short-term effects of isopropyl alcohol to aquatic life, plants, birds, or terrestrial animals.

🕒 *Chronic Ecological Effects*

Chronic toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals.

Insufficient data are available to evaluate or predict the long-term effects of isopropyl alcohol to aquatic life, plants, birds, or land animals.

💧 *Water Solubility*

Isopropyl alcohol is highly soluble in water. Concentrations of 1000 milligrams and more can be expected to mix with a liter of water.

🕒 *Persistence in the Environment*

Isopropyl alcohol is slightly persistent in water, with a half-life of between 2 to 20 days. The half-life of a pollutant is the amount of time it takes for one-half of the chemical to be degraded.

🐟 *Bioaccumulation in Aquatic Organisms*

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans.

The concentration of isopropyl alcohol found in fish tissues is expected to be much lower than the average concentration of isopropyl alcohol in water from which the fish was taken.

🛡️ *Recommended Risk-Reduction Measures*

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in a leak or spill to the environment. The correct use of DOT labeling (per the MSDS) on all containers, trucks, and rail cars will enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of isopropyl alcohol should be segregated from incompatible chemicals to minimize the risk of cross-contamination or contact. Buildings designated for storage should be equipped with appropriate fire protection systems (alarms, sprinklers, emergency lighting, portable extinguishers) and designed to meet appropriate explosion-proof requirements.

If a spill or leak to the environment has occurred, fire department, emergency response, and/or hazardous materials spill personnel should be notified imme-

Risk Management for Hazardous Chemicals

diately. Cleanup should be attempted only by those trained in proper spill containment procedures using non-sparking tools. Contaminated soils should be removed for incineration and replaced with clean soil.

If isopropyl alcohol should contact the water table, aquifer, or navigable waterway, time is of the essence. It is highly soluble in water and, therefore, total containment and remediation may not be possible. When such spills occur, the local and/or state emergency response authorities must be notified. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of isopropyl alcohol. If isopropyl alcohol is spilled or leaked, the following specific steps are recommended to ensure the protection of personnel and the environment:

- ☑ Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened for normal work.
- ☑ Ventilate area and remove ignition sources.
- ☑ Absorb liquids in vermiculite, dry sand, earth, or a similar material and deposit in sealed containers for disposal. Use non-sparking tools.
- ☑ It may be necessary to dispose of isopropyl alcohol as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving isopropyl alcohol can present a moderate threat to business operations. The loss or damage of equipment or facilities can significantly affect fiscal viability. Lawsuits that may result from personnel injury/death, public exposures, and/or environmental contamination will also require a serious expenditure of resources. Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business. Always remember that anytime the terms "cancer," "carcinogen," or reproductive hazard are used, public emotion, hysteria, and ignorance can run equally high. This must be properly considered during the development of any public relations policies.

☉ Recommended Risk-Reduction Measures

Company attorneys, safety and health professionals, and environmental specialists should be involved in

the development of any procedures or policies intended to manage the use of chemicals in the workplace. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

| 3 | 4 | 0 | | 0 = Minimum Hazard 1 = Slight Hazard 2 = Moderate Hazard 3 = Serious Hazard 4 = Severe Hazard | HEALTH = BLUE FIRE = RED REACTIVITY = YELLOW OTHER = WHITE | OX = Oxidizer ACID = Acid ALK = Alkali COR = Corrosive W = Use No Water |

SECTION I - GENERAL INFORMATION

| | | |
|--|---|--|
| Characterization Aliphatic Amine | RCRA Number D001 | EPA Class Characteristic (I) Waste |
| DOT Proper Shipping Name Isopropylamine | Chemical Abstract Service (CAS) Number 75-31-0 | |
| DOT Hazard Class and Label Requirements Flammable Liquid | DOT Emergency Guide Code 68 | |
| DOT Identification Number UN 1221 | Chemical Formula (CH₃)₂CHNH₂ | |

Synonyms

2-Aminopropane; monoisopropylamine; 2-propylamine; sec-propylamine; 2-propanamine.

SECTION II - HAZARDOUS INGREDIENTS AND IDENTITY INFORMATION

| Hazardous Components (specific identity) | OSHA Exposure Criteria | NIOSH Exposure Criteria | Immediately Dangerous to Life and Health (IDLH) | ACGIH Exposure Criteria |
|---|---|---|---|--|
| Isopropylamine (derivation: From the reaction of acetone and ammonia under pressure; by reacting isopropyl alcohol with ammonia in the presence of a dehydrating catalyst; or by reacting isopropyl alcohol and ammonia under pressure). 1 ppm = 2.46 mg/m³ | PEL: 5 ppm 12 mg/m³ STEL: Not Established | REL: Not Established STEL: Not Established | 750 ppm | TLV: 5 ppm 12 mg/m³ STEL: 10 ppm 24 mg/m³ |

SECTION III - PHYSICAL AND CHEMICAL CHARACTERISTICS

| | |
|---|--|
| Boiling Point 91°F (32°C) | Specific Gravity (H ₂ O = 1) 0.69 |
| Vapor Pressure (mm Hg) 478 at 68°F (20°C) | Molecular Weight 59.1 |
| Vapor Density (Air = 1) 2.0 | Melting Point -150°F (-101°C) |

Solubility

Soluble in water, acetone, alcohol, benzene, chloroform, and ether.

Appearance and Odor

Colorless liquid with a strong ammonia-like odor. A gas above 91°F (32°C). Odor Threshold = 5 ppm.

SECTION IV - FIRE AND EXPLOSION HAZARD DATA

| | |
|--|---|
| Flash Point (method used) -35°F (-37°C) opened cup | Explosive Limits in Air % by Volume LEL: 2.3% UEL: 10.4% |
| NFPA Classification Class IA Flammable Liquid | Autoignition Temperature 756°F (402°C) |

Extinguishing Media

Use dry chemical, carbon dioxide, regular foam, or water spray (water may not be effective by itself).

Special Fire Fighting Procedures

Poisonous gases are produced in fire; wear full protective clothing and self-contained breathing apparatus (SCBA). Vapors are heavier than air and may travel for some distance to ignition source and flashback. Move containers from fire area if it can be done safely. Cool exposed containers with water.

Unusual Fire and Explosion Hazards

Containers may explode in fire due to buildup of excessive internal pressures. Exercise extreme caution when attempting to move or relocate containers that may have been exposed to high heat. A boiling liquid expanding vapor explosion (BLEVE) can occur when isopropylamine is involved in fire. Evacuate area if rising sound is heard coming from venting device or tanks are discoloring due to fire.

SECTION V - REACTIVITY DATA

| | | |
|---------------------------------|----------------------------|--|
| Stability | | Conditions to Avoid Isopropylamine is normally stable under routine conditions of handling and storage. Avoid contact with incompatible materials. Keep away from heat and flame. |
| Stable X | Unstable | Incompatibility (<i>materials to avoid</i>) Oxidizing agents (such as chlorine, bromine, and oxygen) and other oxidizable materials, strong acids, aldehydes, ketones, and epoxides. |
| Hazardous Polymerization | | Conditions to Avoid Under normal conditions of temperature and pressure, hazardous polymerization of isopropylamine is not expected to occur. |
| May Occur | Will Not Occur X | Hazardous Decomposition or By-products Toxic and irritating oxides of nitrogen are produced when isopropylamine is heated to decomposition or involved in a fire. These include oxides of carbon and nitrogen. |

SECTION VI - HEALTH HAZARD DATA

| | | | |
|-----------------------------------|-------------------------|--------------------------------|------------------------|
| Primary Route(s) of Entry: | Inhalation? X | Absorption (skin)? X | Ingestion? X |
|-----------------------------------|-------------------------|--------------------------------|------------------------|

Health Hazards

INHALATION: Irritation of the nose, throat, and lungs. Will cause coughing, nausea, headache, and may cause vomiting. May cause fluid buildup in lungs (pulmonary edema) and death.

ABSORPTION: A severe irritant. Eye contact will cause irritation and inflammation. Skin contact causes irritation, inflammation, redness, blistering, and possible sensitization or dermatitis.

INGESTION: Poison by ingestion. Irritation of the mouth, throat, stomach, and digestive tract. Will also cause excessive salivation, nausea, and vomiting.

| | | | | |
|---|-------------|---------------------------|---------------------------------------|--|
| Carcinogenicity | NTP Listed? | IARC Cancer Review Group? | OSHA Regulated? | Target Organs? |
| Unknown Human Unknown Animal | No | No | 29 CFR 1910.1000 Table Z-1 | Eyes; skin; respiratory system. |

Medical Conditions Generally Aggravated by Exposure

Respiratory system disorders and any skin diseases may be aggravated by exposure.

Emergency and First-aid Procedures

Eye contact: Flush immediately with water for 15 minutes (minimum); seek medical attention. **Skin contact:** Remove all contaminated clothing. Immediately wash area with large amounts of soap and water. Seek medical assistance. For **inhalation:** Remove the person from exposure. Provide respiratory assistance and CPR. Transfer to medical facility. Observe for 24-48 hours for lung effects. If **swallowed:** Call the poison control center; seek medical attention immediately. Give 1-2 glasses of water to dilute. Do NOT induce vomiting. Never attempt to give an unconscious person anything by mouth.

SECTION VII - PRECAUTIONS FOR SAFE HANDLING AND USE

Steps to be Taken in Case Material is Released or Spilled

Absorb liquids in vermiculite or other absorbent and deposit in DOT-approved drum. Small spills may be absorbed in paper towels and evaporate in fume hood. Ventilate area and remove ignition sources. Restrict those not involved in cleanup from entering area. Notify appropriate authorities, if applicable.

Preferred Waste Disposal Method

Burn in a chemical incinerator equipped with a scrubber and afterburner.

Precautions to be Taken in Handling and Storage

Do not store isopropylamine in the presence of incompatible chemicals or materials. Store in tightly closed containers in a cool, well-ventilated area. Personnel working with isopropylamine should be trained on its proper handling and storage prior to being assigned to such responsibilities.

Other Precautions and Warnings

To prevent static sparks, electrically ground and bond all containers and equipment.

SECTION VIII - CONTROL MEASURES AND PERSONAL PROTECTIVE EQUIPMENT

Respiratory Protection (*specify type*)

Exposure levels are low and difficult to accurately monitor. For low or infrequent exposures, use an organic vapor respirator. Greater protection at higher exposures is provided with an MSHA/NIOSH-approved supplied-air respirator with full facepiece operated in continuous flow or other positive pressure mode (pressure demand), or a self-contained breathing apparatus (SCBA) with full facepiece operated in pressure demand or other positive pressure mode.

Ventilation

Local exhaust or general mechanical systems recommended.

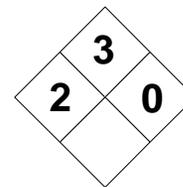

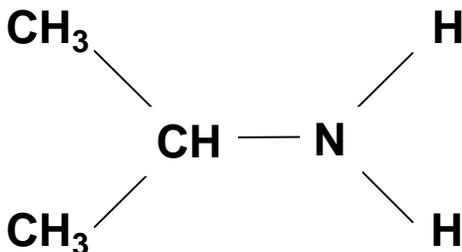

| | | |
|---|--|--|
| Protective Gloves Impervious Material | Eye Protection Chemical Goggles or Face Mask | Other Protective Clothing Protective Apron |
|---|--|--|

Work/Hygiene Practices

Always wash hands thoroughly after using chemical; never bring food, drink, or smoking materials into vicinity of chemicals.

ISOPROPYLAMINE

CAS: 75-31-0

**IDENTIFICATION AND TYPICAL USES**

Isopropylamine is a colorless or clear liquid with a strong, ammonia-like odor. It can exist as a gas at temperatures above 91°F (32°C). It is used in the synthesis of rubber accelerators, in pharmaceuticals, in dyes, in insecticides, in certain textile specialties, in surface-active agents, and as a dehairing agent.

RISK ASSESSMENT: HEALTH**General Assessment**

Isopropylamine is a human poison by skin contact (*absorption*), is moderately toxic by *ingestion* and mildly toxic by *inhalation*. It is also moderately toxic by skin contact (irritant). It will irritate the nose and throat (mucous membranes) and is a severe eye and skin irritant. There are no data on its carcinogenic, mutagenic, or teratogenic capabilities.

Inhalation will cause irritation to the nose, throat, and especially the lungs. It will cause cough, nausea, and headache. Its respiratory toxicity is primarily due to pulmonary effects. On high exposures, it may cause a fluid buildup in the lungs (pulmonary edema) which is a medical emergency and can be fatal. Symptoms may be delayed up to 48 hours, thereby creating a false sense of security relative to exposure risk.

Ingestion will result in digestive system irritation, unspecified but adverse gastrointestinal effects with irritation of the mouth, throat (esophagus), and stomach. There may be excessive salivation, nausea, vomiting, cramps, and headache.

Skin contact with the vapor or the liquid results in severe irritation and may produce dermatitis with drying, redness, rash, and itching. Some individuals may become sensitized. Eye contact with the vapor can result in severe irritation with corneal edema. The

liquid may cause serious burns and permanent damage to eye tissues and possibly to vision.

☠ Acute Health Effects

The following acute (short-term) health effects may occur either immediately or shortly after (within hours or days) exposure to isopropylamine:

Skin: Irritation, inflammation, redness (erythema), itching, and possible sensitization and/or dermatitis.

Eye: Severe irritation, inflammation, and possible damage to the cornea and to vision.

Lung: Irritation causing coughing and/or shortness of breath. Higher exposures can lead to respiratory problems, including pulmonary edema (fluid buildup in lungs) which is a medical emergency and can be fatal.

☘ Chronic Health Effects

The following chronic (long-term) health effects may occur at some time after exposure to isopropylamine and can last for months or even years:

Cancer Hazards: According to the information presented in the references, isopropylamine has not been adequately tested for its ability to cause cancer in test animals.

Reproductive Hazard: According to the information presented in the references, isopropylamine has not been adequately tested for its ability to adversely affect reproduction.

Other Chronic Effects: Low, chronic exposures to skin may cause allergy, sensitization, or dermatitis.

🔧 Recommended Risk-Reduction Measures

Unless a less toxic chemical can be substituted for a hazardous substance, *engineering controls* are the most effective method of reducing exposures. The best protection is to enclose operations and/or provide local exhaust ventilation at the site of chemical release. While not always operationally feasible, isolating operations can also reduce exposure.

Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around isopropylamine. The exposure level for this compound is extremely low and difficult to accurately monitor. For relatively low, infrequent, or transient exposures, an organic vapor respirator may suffice. However, for higher or prolonged exposure, a self-contained breathing apparatus (SCBA) with full facepiece operated in pressure demand or a powered air-purifying respirator operated in continuous flow mode are the recommended respiratory protection methods of choice. If a full facepiece is not available, then chemical goggles should be worn to protect the eyes. Whenever a chemical splash hazard exists, a face shield and apron should be worn. To prevent hand and skin exposures, impervious gloves should be worn. Butyl rubber may be used with caution for short periods (less than 4 hours). Natural rubber, neoprene, nitrile rubber, polyvinyl alcohol, polyvinyl chloride, and Viton are *not* suitable protection. Glove manufacturers should be contacted and permeation studies obtained *before* final glove selections have been made.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with isopropylamine.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where isopropylamine is used or stored.

Before beginning employment and at regular intervals thereafter (e.g. annually), the following medical tests are recommended:

- Lung function tests (establish a baseline).

If symptoms develop or overexposure is suspected, the following medical tests may be useful:

- Lung function tests (compare to baseline).

- Consider chest X-ray after acute overexposure (may be negative if performed immediately after exposure or if symptoms have not yet appeared).
- Evaluation by a qualified allergist with careful evaluation of exposure history and administration of special tests (may help diagnose skin allergy).
- Urinalysis (isopropylamine is metabolized as acetone and ammonia).
- Complete blood count (CBC) with sedimentation rate, serum electrolysis, calcium, phosphorus, albumin, total protein, and arterial blood gases.

Any evaluation should include a careful medical history of past and present symptoms with an examination. However, medical tests that evaluate existing damage are not a substitute for controlling exposure. Also, since smoking can cause heart disease, emphysema, and numerous other respiratory disorders, smokers may be affected more rapidly than non-smokers to the same exposure conditions. Prudent risk assessment and management requires careful consideration of *all* possible risk factors that may be causing the appearance of symptoms in exposed workers.

Other methods to reduce exposure include:

- Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not used, respiratory protection should be mandatory. Also, if possible, automatically transfer liquids from storage containers to process containers using non-sparking tools.
- Always ensure that proper protective clothing is worn when using chemical substances and that personnel are trained on its use and care.
- Wash thoroughly immediately after exposure to isopropylamine and at the end of the work shift or before eating, drinking, or smoking.
- Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of isopropylamine should be communicated to all exposed and potentially exposed workers.
- Eye wash stations should be provided in work areas. If the potential for whole body exposure exists, then safety showers should also be provided.

RISK ASSESSMENT: ENVIRONMENT

General Assessment

The environment is at risk of exposure during intended use, transportation, storage, disposal, or destruction of isopropylamine. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance. Accidental spills, large or small, can result in fire, explosion, and possible contamination of the surrounding environmental mediums (water, soil, and air).

Isopropylamine is considered a Class IA flammable liquid (per OSHA 29 CFR 1910.106). Its extremely low flash point and relatively low boiling point present a dangerous fire and explosion hazard, especially in confined areas or under conditions of extreme heat. It can react with many common oxidizing materials to cause a fire or explosion. Its vapors are heavier than air and can travel for great distances to an ignition source to flashback and cause fire or explosion. These characteristics require special consideration during any emergency situation involving a leak or spill of isopropylamine. Should isopropylamine ever come into contact with incompatible substances such as oxidizers, acids, aldehydes, ketones, or epoxides, either during use, transportation, or storage, violent reactions can occur.

Isopropylamine can enter the environment through industrial discharges, municipal waste treatment plant discharges, and from spills.

☠ *Acute Ecological Effects*

Acute (short-term) toxic effects may include the death of animals, birds, or fish and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to isopropylamine.

Isopropylamine has slight acute toxicity to aquatic life. Insufficient data are available to evaluate or predict the short-term effects of isopropylamine to plants, birds, or land animals.

🕒 *Chronic Ecological Effects*

Chronic toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals.

Insufficient data are available to evaluate or predict the long-term effects of isopropylamine to aquatic life, plants, birds, or land animals.

💧 *Water Solubility*

Isopropylamine is highly soluble in water. Concentrations of 1000 milligrams or more will mix with a liter of water.

🕒 *Persistence in the Environment*

Isopropylamine is moderately persistent in water, with a half-life of between 20 to 200 days. The half-life of a pollutant is the amount of time it takes for one half of the chemical to be degraded. It is expected to be highly mobile in terrestrial soils.

🐟 *Bioaccumulation in Aquatic Organisms*

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans.

The concentration of isopropylamine found in the edible tissues of fish is expected to be much lower than the average concentration in the water from which the fish was taken.

🛡️ *Recommended Risk-Reduction Measures*

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in a leak or spill to the environment. The correct use of DOT labeling (per the MSDS) on all containers, trucks, and rail cars will enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of isopropylamine should be segregated from incompatible chemicals to minimize the risk of cross-contamination or contact. Storage buildings should be equipped with the proper fire protection equipment (alarms, sprinklers, extinguishers, etc.).

If a spill or leak to the environment has occurred, fire department, emergency response and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those trained in proper spill containment procedures using non-sparking tools. Contaminated soils should be removed for incineration and replaced with clean soil. If isopropylamine should contact the water table, aquifer, or navigable waterway, remediation activities should be prompt to ensure protection of aquatic sediments. When such spills occur, the local and/or state emergency response authorities must be notified. A comprehensive emergency response or disaster pre-

paredness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of isopropylamine. If isopropylamine is spilled or leaked, the following specific steps are recommended:

- ☑ Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened for normal work.
- ☑ Ventilate area and remove all ignition sources.
- ☑ Absorb liquid spills using vermiculite, dry earth, or sand to absorb and place in a sealed drum for disposal. Use non-sparking tools.
- ☑ It may be necessary to dispose of isopropylamine as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving isopropylamine can present a significant threat to business operations. The loss or damage of equipment or facilities can significantly affect fiscal viability. Lawsuits that may result from personnel injury/death, public exposures, and/or environmental contamination will also require a serious expenditure of resources. Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business.

Recommended Risk-Reduction Measures

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures dealing with safety or emergency response. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

| NFPA Classification | Class IB Flammable Liquid | Autoignition Temperature | |
| | | 830°F (443°C) | |

Extinguishing Media

Dry chemical, alcohol-resistant foam, or carbon dioxide. Use water spray to keep fire-exposed containers cool. Water itself may be ineffective on fire since isopropyl ether floats on water.

Special Fire Fighting Procedures

Wear full protective clothing and self-contained breathing apparatus (SCBA). Move container from fire area if it can be done without risk. Use water spray to flush spills from ignition sources and to knock down vapors that have not yet ignited. Treat as a gas fire; use blanketing effect to smother flames.

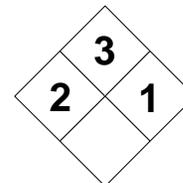

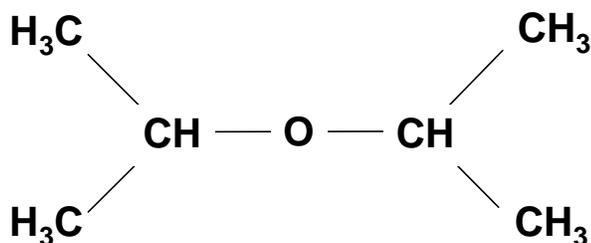

Unusual Fire and Explosion Hazards

Containers may explode in fire. Presents a vapor explosion hazard indoors, outdoors, and in sewers.

| SECTION V - REACTIVITY DATA | | | | |
|---|---|---|--|---|
| Stability | | Conditions to Avoid Isopropyl ether is NOT stable under normal conditions of handling and storage. It can form unstable peroxides and hydroperoxides on exposure to air. Peroxide can explode if distilled or heated. | | |
| Stable | Unstable X | Incompatibility (<i>materials to avoid</i>) Incompatible with strong oxidizers, peroxides, permanganates, acids (chlorosulfonic acid, nitric acid), and propionyl chloride. | | |
| Hazardous Polymerization | | Conditions to Avoid Under normal conditions of temperature and pressure, hazardous polymerization of isopropyl ether is not expected to occur. Do not store more than a six-month supply. | | |
| May Occur | Will Not Occur X | Hazardous Decomposition or By-products When heated to decomposition, isopropyl ether emits acrid smoke and fumes, including toxic carbon dioxide gas and fumes. | | |
| SECTION VI - HEALTH HAZARD DATA | | | | |
| Primary Route(s) of Entry: | | Inhalation? X | Absorption (skin/eye)? | Ingestion? X |
| Health Hazards INHALATION: Causes headache, nausea, vomiting, loss of consciousness and, at high concentrations, death. Depression of the central nervous system (CNS) causing anesthesia, exhaustion, loss of appetite, sleepiness, dizziness, excitation, anorexia, giddiness, narcotic effects. SKIN & EYES: An eye and skin irritant. May lead to dermatitis on prolonged contact and it can also cause conjunctivitis. May cause skin burns and eye irritation (smarting). INGESTION: Not likely, but possible. The liquid evaporates rapidly making ingestion unlikely. | | | | |
| Carcinogenicity Unknown Human Unknown Animal | NTP Listed? No | IARC Cancer Review Group? No | OSHA Regulated? 29 CFR 1910.1000 Table Z-1 | Target Organs? Skin, eyes, respiratory system, CNS, |
| Medical Conditions Generally Aggravated by Exposure Any nervous system disorders may be aggravated by exposure. | | | | |
| Emergency and First-aid Procedures Eye contact: Do not allow victim to keep eyes tightly shut. Flush immediately with water for 15 minutes (minimum); seek medical attention. Skin contact: No serious hazard since evaporation is quick. Prolonged contact may cause drying, cracking, or burning. Contaminated clothing should be removed (fire hazard). Wash area with large amounts of soap and water. For inhalation: Remove the person from exposure. Provide respiratory assistance and CPR. Transfer to medical facility. If swallowed: Not very likely. Seek medical attention immediately. Unless advised otherwise, give 1-2 glasses of water to dilute. Do NOT induce vomiting because of danger of aspiration (breathing the liquid into the lungs). Gastric lavage may be advised. Never attempt to give an unconscious or convulsing person anything by mouth. | | | | |
| SECTION VII - PRECAUTIONS FOR SAFE HANDLING AND USE | | | | |
| Steps to be Taken in Case Material is Released or Spilled Wear self-contained breathing apparatus (SCBA). Restrict those not wearing protective equipment and who are not involved in cleanup from area. Avoid skin contact. Ventilate area of spill and remove ignition sources. Absorb liquids in vermiculite, collect with non-sparking tools, and deposit in sealed drum. | | | | |
| Preferred Waste Disposal Method Mix with a higher-boiling solvent and burn in chemical incinerator with afterburner and scrubber. | | | | |
| Precautions to be Taken in Handling and Storage Store in tightly closed (air-tight), metal containers in a cool, dry, well-ventilated area away from heat and incompatible materials. Control inventories. Protect containers from physical damage. | | | | |
| Other Precautions and Warnings Before using bulk material, test small quantity to ascertain quality and peroxide content. | | | | |
| SECTION VIII - CONTROL MEASURES AND PERSONAL PROTECTIVE EQUIPMENT | | | | |
| Respiratory Protection (<i>specify type</i>) Use a NIOSH-approved air-purifying respirator for low levels. Best protection is obtained using a supplied-air respirator or a SCBA with full facepiece operated in positive pressure mode. | | | | |
| Ventilation Local exhaust (preferred) at site of chemical work or general ventilation. | | | | |

| Work/Hygiene Practices Always wash hands thoroughly after using chemical; never bring food, drink, or smoking materials into vicinity of chemicals. | | | | |

ISOPROPYL ETHER

CAS: 108-20-3

**IDENTIFICATION AND TYPICAL USES**

Isopropyl ether appears as a clear, colorless, volatile, mobile, water-white liquid with a characteristic, sweet, pungent, aromatic, ethereal odor and bitter-sweet taste. It is used as a solvent for animal, vegetable, and mineral oils, waxes, and resins. It is also used in the extraction of acetic acid from aqueous solutions. It is a solvent for dyes (in the presence of small quantities of alcohol). It is used in spotting compositions, and in the manufacture of rubber cements.

RISK ASSESSMENT: HEALTH**General Assessment**

Isopropyl ether is a narcotic substance and is considered mildly to moderately toxic by *inhalation* and skin contact, although dermal absorption has not been reported as a route of entry into the body. *Ingestion* may also be an exposure route. However, the liquid is extremely volatile, evaporating quickly and making ingestion possible but improbable. There are no reports to indicate that this chemical poses carcinogenic, mutagenic, or teratogenic effects in humans.

Inhalation of isopropyl ether vapors causes anesthetic effects because of the chemical's ability to quickly and effectively depress the central nervous system. Symptoms of exposure include exhaustion, loss of appetite, sleepiness, dizziness, headache, giddiness, excitation, nausea, vomiting, anorexia, loss of consciousness, possible seizures and convulsions, psychic disturbances, and death due to respiratory arrest. Exposure can cause irritation of the eyes, nose, throat, and respiratory system with subsequent changes (numbing) of the sense of smell.

Skin contact with the liquid poses no serious threat because isopropyl ether will evaporate rather quickly. However, if allowed to remain in contact (in

wet clothing, for example) for extended periods, there can be drying, cracking, even some burning of the skin's surface. Repeated skin contact may lead to dermatitis. The vapors will cause irritation and smarting of the eyes. Conjunctivitis is also possible, especially on exposure to heavy vapor concentrations.

Ingestion is not likely since the liquid will evaporate quickly, leaving very little time for ingestion. However, it is a remote possibility and the symptoms of inhalation can be expected to occur.

☠ Acute Health Effects

The following acute (short-term) health effects may occur immediately or shortly after exposure to isopropyl ether:

Skin: Irritation with drying, cracking, secondary infection, and possible dermatitis.

Eye: Irritation, smarting of eye tissues and associated skin surfaces (lids), and conjunctivitis.

Lung: Irritation to respiratory tract causing cough and sore throat. May also cause olfactory changes (numbing of the sense of smell). Absorption through respiration causes anesthetic effects and narcosis (deep unconsciousness).

CNS: Rapid depression of the central nervous system causing a variety of toxic effects including loss of coordination and consciousness, and even death due to respiratory arrest.

☘ Chronic Health Effects

The following chronic (long-term) health effects may occur at some time after exposure to isopropyl ether and can last for months or even years:

Cancer Hazards: There is no evidence in the references that exposure to isopropyl ether causes cancer in animals or humans. Additional research is required in this area of study before any conclusions can be made.

Reproductive Hazard: According to the references, isopropyl ether has not been adequately tested for its ability to adversely affect reproduction.

Other Chronic Effects: Repeated low-dose exposures can cause chronic dermatitis.

🕒 **Recommended Risk-Reduction Measures**

Personnel should avoid direct contact with isopropyl ether. Its specific toxicity is not clearly understood in the references. If a less toxic material or compound cannot be substituted for isopropyl ether, then *engineering controls* are the most effective method of reducing exposure risk. The best protection is to enclose operations and/or provide local exhaust ventilation at the site of isopropyl ether release. While not always operationally feasible, isolating operations can also reduce exposure. Using respiratory protection is less effective than the controls mentioned above, but is still required whenever working with or around isopropyl ether. For exposures to the PEL (500 ppm), an air-purifying respirator should provide adequate protection. For high exposures or when the concentration is unknown (as in an emergency), an MSHA/NIOSH-approved supplied-air respirator or a self-contained breathing apparatus (SCBA) with full facepiece and operated in pressure demand mode are the recommended methods of respiratory protection. If a full facepiece is not available, then chemical goggles should be worn to protect the eyes, especially when a splash hazard exists. A face shield should also be considered. To prevent hand and skin exposures, polyvinyl alcohol (PVA), polyvinyl chloride (PVC), nitrile rubber, or chlorinated polyethylene gloves should be used. Glove manufacturers should be contacted and permeation studies obtained *before* final glove selections have been made.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with isopropyl ether.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication) prior to the first assignment in an area where isopropyl ether is used or stored.

If symptoms develop or overexposure is suspected, the following may be useful:

- ☑ Liver, kidney, and lung function tests.
- ☑ Evaluation of the central nervous system.

It should be noted that medical tests that simply look for existing damage are not a substitute for controlling exposures. Medical histories are extremely important when assessing exposure risk.

Other methods to reduce exposure include:

- ☑ Always ensure that proper protective clothing is worn when using chemical substances and that personnel are trained in its use and care.
- ☑ Wash thoroughly immediately after exposure to isopropyl ether and at the end of the work shift or before eating, drinking, or smoking.
- ☑ Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of isopropyl ether should be communicated to all exposed or potentially exposed workers.
- ☑ Eye wash stations should be provided in the immediate work area for emergency use. If there is a possibility of skin exposure to isopropyl ether, emergency shower facilities should also be provided in the work area.
- ☑ Workers whose clothing has been contaminated by isopropyl ether should change into clean clothes before leaving work. Contaminated work clothing presents a serious fire hazard and should be laundered only by individuals who have been informed of the hazards of exposure to isopropyl ether.

RISK ASSESSMENT: ENVIRONMENT

General Assessment

The environment is at risk of exposure during transportation, storage, disposal, or destruction of isopropyl ether. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance. Accidental spills, large or small, can result in contamination of the surrounding environmental mediums (primarily air, but water and soil contamination can also occur).

Isopropyl ether is Class IB flammable liquid (per OSHA 29 CFR 1910.106). This presents a dangerous fire and explosion hazard. Its vapors are heavier than air and can travel for some distance to an ignition

source to flashback and cause fire or explosion. It can form explosive peroxides in contact with air or in the presence of a photosensitizer such as benzophenone. Peroxides are shock-sensitive and can easily explode. It is incompatible with many oxidizers and acids and caution is always required in handling, storage, transportation, and disposal of isopropyl ether. When heated to decomposition it emits very acrid and irritating smoke and fumes. Emergency responders should be made aware of the presence of isopropyl ether at any emergency response situation. Isopropyl ether may enter the environment through industrial effluents and spills.

☠ *Acute Ecological Effects*

Acute (short-term) toxic effects may include the death of animals, birds, or fish and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to isopropyl ether. Isopropyl ether has slight acute toxicity to aquatic life. Insufficient data are available to evaluate or predict the acute (short-term) effects of isopropyl ether on plants, birds, or land animals.

🕒 *Chronic Ecological Effects*

Chronic (long-term) toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals. Insufficient data are available to evaluate the chronic (long-term) effects of isopropyl ether on aquatic life, plants, birds, or land animals.

💧 *Water Solubility*

Isopropyl ether is slightly soluble in water. Concentrations of less than 100 milligrams will mix with a liter of water.

🕒 *Persistence in the Environment*

Isopropyl ether is non-persistent in water, with a half-life of less than 2 days. The half-life of a pollutant is the amount of time it takes for one half of the chemical to be degraded. Approximately 100% of isopropyl ether will eventually end up in air.

🐟 *Bioaccumulation in Aquatic Organisms*

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat con-

taminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans.

The references do not address the bioaccumulation capabilities of isopropyl ether in aquatic organisms. However, considering the extremely volatile nature of this chemical, bioaccumulation may not be possible.

🛡️ *Recommended Risk-Reduction Measures*

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in a leak or spill of isopropyl ether into the environment. Labels on all containers, trucks, and rail cars must meet DOT requirements and accurately reflect their contents to enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of isopropyl ether should be segregated from other chemicals to minimize the risk of cross-contamination. Isopropyl ether must be stored to avoid contact with strong oxidizers, such as chlorine and bromine, since violent reactions can occur. Containers should be protected from physical damage and stored to avoid contact with heat, including sunlight. Isopropyl ether must be stored in air-tight containers to prevent the formation of explosive peroxides. Inventories should be controlled and no more than a six-month supply should be kept in storage.

If a spill or leak to the environment has occurred, fire department, emergency response and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those trained in proper spill containment procedures using non-sparking tools. Contaminated soils should be removed for incineration and replaced with clean soil.

If isopropyl ether should contact the water table, aquifer, or navigable waterway, time is of the essence. Its rapid evaporation may make total remediation impossible. The local and/or state emergency response authorities must be notified. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of isopropyl ether.

Isopropyl ether may be disposed of by mixing with an excess of a higher-boiling solvent and then burning in a chemical incinerator equipped with an afterburner and scrubber. If isopropyl ether is spilled or leaked, the following specific steps are recommended:

Risk Management for Hazardous Chemicals

- ☑ Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete. Avoid skin and eye contact.
- ☑ Absorb spilled liquids with vermiculite, dry sand, or a similar material and deposit in sealed drum for disposal. Use non-sparking tools!
- ☑ Ventilate area and remove all ignition sources.
- ☑ It may be necessary to dispose of isopropyl ether as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS***General Assessment***

Accidents or mishaps involving isopropyl ether can present a serious threat to business operations. The loss or damage of equipment or facilities can significantly affect fiscal viability. Lawsuits that may result from personnel illness, injury/death, public exposures, and/or environmental contamination will require a serious expenditure of resources. Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business.

🔍 *Recommended Risk-Reduction Measures*

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures for responding to chemical incidents. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

ISOPROPYL GLYCIDYL ETHER

CAS: 4016-14-2

**IDENTIFICATION AND TYPICAL USES**

Isopropyl glycidyl ether is a clear, colorless, mobile liquid with a mild, ethereal odor. It is used as a stabilizer for chlorinated solvents and organic compounds, and a viscosity reducer for epoxy resins. It is also used as an intermediate for the synthesis of ether and esters.

RISK ASSESSMENT: HEALTH**General Assessment**

Isopropyl glycidyl ether is mildly toxic to humans by *ingestion* and *inhalation*. It will also cause some health effects on contact with the skin, but dermal absorption has not been reported. It is a severe central nervous system depressant. There are no reports in the references to indicate that exposure causes cancer. However, mutation data and reproductive effects have been reported in test animals.

Toxic systemic effects by inhalation can include hemolytic anemia, digestive problems, dizziness, respiratory distress, and liver dysfunction. Symptoms of exposure can include abdominal pain, nausea, vomiting, general weakness and muscle tenderness, and possible changes in the hematopoietic system (blood-producing organs, such as bone marrow). CNS depression may cause excitement or exhilaration, drunkenness and stupor, ataxia, dizziness, coma, and possible convulsions.

Eye contact may produce mild to moderate irritation and skin contact may cause an allergic reaction, rash, and possible dermatitis. If ingested, this compound will cause unspecified gastrointestinal effects.

☠ Acute Health Effects

The following acute (short-term) health effects may occur immediately or shortly after exposure to isopropyl glycidyl ether:

Skin: Some irritation at site of contact. Allergic rash with irritation can occur.

Eye: Mild to moderate irritation.

Lung: Nose and throat irritation. Produces intoxicating effects and may cause lung effects.

CNS: Stimulation and depression with symptoms of dizziness, headache, lightheadedness, nausea, vomiting, and coma.

☘ Chronic Health Effects

The following chronic (long-term) health effects may occur at some time after exposure to isopropyl glycidyl ether and can last for months or even years:

Cancer Hazards: According to information presented in the references, isopropyl glycidyl ether has not been adequately tested for its ability to cause cancer in animals. Some mutation data have been reported in test animals. Some scientists believe that such chemicals may have the potential to cause cancer in the long-term. It is not known if exposure to isopropyl glycidyl ether will have this effect on humans.

Reproductive Hazard: According to information presented in the references, isopropyl glycidyl ether has been shown to adversely affect reproduction in test animals.

Other Chronic Effects: Repeated exposures may cause changes in blood-producing organs (bone marrow). These changes may include the development of hemolytic anemia (destruction of red blood cells). Skin rash and/or dermatitis may develop following prolonged or repeated contact.

🛡 Recommended Risk-Reduction Measures

Personnel should avoid direct contact with isopropyl glycidyl ether. This chemical is toxic to humans by inhalation and ingestion. If a less toxic chemical can-

not be substituted for a hazardous substance, then *engineering controls* are the most effective method of reducing exposures. The best protection is to enclose operations and/or provide local exhaust ventilation at the site of chemical release. While not always operationally feasible, isolating operations can also reduce exposure. Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around isopropyl glycidyl ether. Chemical cartridge respirators may provide adequate protection over the PEL. However, the best protection is obtained using a supplied-air respirator with full facepiece operated in continuous flow mode, or a self-contained breathing apparatus (SCBA) with full facepiece operated in pressure demand. If a full facepiece is not available, then chemical goggles should be worn to protect the eyes. Whenever a chemical splash hazard exists, a face shield and a protective apron should be worn. To prevent hand and skin exposures, impervious gloves should be used. Glove manufacturers should be contacted and permeation studies obtained *before* final glove selections have been made.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with or around isopropyl glycidyl ether.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where isopropyl glycidyl ether is used or stored.

If symptoms develop or overexposure is suspected, the following tests are recommended:

- Kidney function tests.
- Urinalysis.
- Evaluation by a qualified allergist with careful consideration of exposure history and special testing (may help diagnose skin allergy).

Any evaluation should include a careful history of past and present symptoms with an examination. Medical tests that simply look for existing damage are not a substitute for controlling exposures.

Other methods to reduce exposure include:

- Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not used, respiratory protection should be mandatory.

- Where possible, automatically transfer liquid isopropyl glycidyl ether from storage drums to process containers. Electrically ground and bond all containers and equipment, especially during transfer operations.
- Always ensure that proper protective clothing is worn when using chemical substances and that personnel are trained in its use and care.
- Wash thoroughly immediately after exposure to isopropyl glycidyl ether and at the end of the work shift or before eating, drinking, or smoking.
- Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards associated with isopropyl glycidyl ether should be communicated to all potentially exposed workers.
- Eye wash stations should be provided in the immediate work area for emergency use. If there is a possibility of skin exposure to this chemical, then emergency shower facilities should also be provided in the immediate work area.
- Personnel should never wear contaminated clothing home (family members can be exposed). Clothing should be laundered only by personnel who have been properly trained on hazards associated with exposure to isopropyl glycidyl ether.

RISK ASSESSMENT: ENVIRONMENT

General Assessment

The environment is at risk of exposure during transportation, storage, disposal, or destruction of isopropyl glycidyl ether. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance. Accidental spills, large or small, can result in fire, explosion, and possible contamination of the surrounding environmental mediums (water, soil, and air).

Isopropyl glycidyl ether is considered a Class IC flammable liquid (per OSHA 29 CFR 1910.106). Its relatively low flash point and moderate boiling point present a serious fire and explosion hazard, especially in confined spaces. Its vapors are heavier than air and can travel for great distances to an ignition source to flashback and cause fire or explosion. It can form explosive peroxides on exposure to air or light. These characteristics require extreme caution in handling, storage, transportation, and disposal. It is incompatible with many common peroxides and other oxidizers and contact can cause fire or explosion. Therefore,

special consideration is required during any emergency situation involving a leak or spill of isopropyl glycidyl ether. Should isopropyl glycidyl ether ever come into contact with any incompatible substances during use, transportation, storage, or disposal, the formation of highly toxic and/or highly explosive commodities is extremely possible.

The proper method for disposing of waste isopropyl glycidyl ether is to burn it in a chemical incinerator equipped with an afterburner and scrubber.

Isopropyl glycidyl ether may enter the environment through industrial or municipal waste treatment plant discharges, agricultural runoff or disposal, or spills.

☠ *Acute Ecological Effects*

Acute (short-term) toxic effects may include the death of animals, birds, or fish and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to isopropyl glycidyl ether.

Insufficient data are available to evaluate or predict the short-term effects of isopropyl glycidyl ether exposure to aquatic life, plants, birds, or land animals.

🕒 *Chronic Ecological Effects*

Chronic (long-term) toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after (sometimes months or even years) first exposure(s) to toxic chemicals.

Insufficient data are available to evaluate or predict the long-term effects of isopropyl glycidyl ether exposure on aquatic life, birds, plants, or land animals.

💧 *Water Solubility*

Isopropyl glycidyl ether is moderately soluble in water. Concentrations up to 1000 milligrams will mix with a liter of water.

🕒 *Persistence in the Environment*

Isopropyl glycidyl ether is slightly persistent in water, with a half-life between 2 and 20 days. The half-life of a pollutant is the amount of time it takes for one half of the chemical to be degraded. There is insufficient data to evaluate the distribution of isopropyl glycidyl ether in the various environmental mediums (air, water, soil).

🐟 *Bioaccumulation in Aquatic Organisms*

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans.

No data are available on the bioaccumulation properties of isopropyl glycidyl ether.

🛡️ *Recommended Risk-Reduction Measures*

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in a leak or spill to the environment. The correct use of DOT labeling (per the MSDS) on all containers, trucks, and rail cars will enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of isopropyl glycidyl ether should be segregated from incompatible chemicals to minimize the risk of cross-contamination or contact. Buildings designated for storage should be equipped with appropriate fire protection systems (alarms, sprinklers, emergency lighting, portable extinguishers). Containers and equipment should be grounded and bonded, especially during transfer operations. Inventories should be monitored to ensure supplies are not kept in storage for extended periods (e.g., more than six months).

If a spill or leak to the environment has occurred, fire department, emergency response and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those trained in proper spill containment procedures using non-sparking tools. Contaminated soils should be removed for incineration and replaced with clean soil. If isopropyl glycidyl ether should contact the water table, aquifer, or navigable waterway, cleanup should be started immediately. It is highly soluble in water and total remediation may not be possible. The local and/or state emergency response authorities must be notified. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of isopropyl glycidyl ether. If this chemical is spilled or leaked, the following specific steps are recommended:

- Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened for normal work.
- Remove all ignition sources.
- Ventilate area of spill or leak.

- ☑ Absorb liquids in vermiculite, dry sand, earth, or similar material and deposit in sealed containers using non-sparking tools.
- ☑ It may be necessary to dispose of this compound as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving isopropyl glycidyl ether can present a significant threat to business operations. The loss or damage of equipment or facilities can significantly affect fiscal viability. Lawsuits that may result from personnel injury/death, public exposures, and/or environmental contamination will also require a serious expenditure of resources. Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business. Always remember that anytime the term “reproductive hazard” is used, public hysteria, ignorance, and emotion can run equally high. This must be carefully considered whenever developing or implementing public relations policies.

☉ Recommended Risk-Reduction Measures

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures dealing with safety or emergency response. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

| Primary Route(s) of Entry: | | Inhalation? X | Absorption (skin/eye)? | Ingestion? X |
| Health Hazards INHALATION: Symptoms include irritation of the nose, throat, and mucosa of the respiratory tract with headache and drowsiness. High concentrations can cause feeling of suffocation, coma, pulmonary edema, and death (respiratory arrest). Chronic exposures can lead to serious central nervous system effects and neurological impairment. SKIN & EYES: Irritation with drying, cracking, redness, blistering (prolonged contact). May lead to contact dermatitis and secondary infection. INGESTION: May cause nausea, vomiting, headache and gastrointestinal irritation. Aspiration of vomit into the lungs can cause serious pneumonitis and even pulmonary hemorrhage. | | | | |
| Carcinogenicity Unknown Human Unknown Animal | NTP Listed? No | IARC Cancer Review Group? No | OSHA Regulated? No | Target Organs? Eyes, skin, respiratory sys., liver, CNS, kidneys. |
| Medical Conditions Generally Aggravated by Exposure Chronic pulmonary disease may be aggravated by exposure. | | | | |
| Emergency and First-aid Procedures Eye contact: Do not allow victim to keep eyes tightly shut. Flush immediately with water for 15 minutes (minimum); seek medical attention. Skin contact: Remove all contaminated clothing, including shoes. Immediately wash area with flooding amounts of soap and water. Seek medical attention if blisters develop. For inhalation: Remove the person from exposure. Provide respiratory assistance and CPR. Transfer to medical facility. Observe for 48 hours for lung effects. If swallowed: Seek medical attention immediately. Give conscious person milk or water to drink. Do NOT induce vomiting. | | | | |
| SECTION VII - PRECAUTIONS FOR SAFE HANDLING AND USE | | | | |
| Steps to be Taken in Case Material is Released or Spilled Remove all ignition sources. Wear SCBA respiratory protection. Avoid skin contact. Stop leak if it can be done without risk. Provide maximum explosion-proof ventilation. Absorb with vermiculite or other similar material and deposit in sealed containers. Use non-sparking tools during cleanup. | | | | |
| Preferred Waste Disposal Method No citation. | | | | |
| Precautions to be Taken in Handling and Storage Store in tightly closed containers in cool, well-ventilated location. Keep away from sources of heat. | | | | |
| Other Precautions and Warnings Sources of ignition such (open flame or smoking), are prohibited where jet fuel is used or stored. Metal containers should be bonded and grounded during transfer operations. Bulk storage not recommended. | | | | |
| SECTION VIII - CONTROL MEASURES AND PERSONAL PROTECTIVE EQUIPMENT | | | | |
| Respiratory Protection (<i>specify type</i>) Use an MSHA/NIOSH-approved air-purifying organic vapor respirator, a powered air-purifying respirator, or a self-contained breathing apparatus (SCBA) with full facepiece operated in positive pressure mode. | | | | |
| Ventilation Local exhaust (preferred) at site of chemical work or general ventilation. | | | | |
| Protective Gloves Impervious Material | Eye Protection Chemical Goggles or Face Mask | Other Protective Clothing Protective Apron if Splash is Likely | | |
| Work/Hygiene Practices Always wash hands thoroughly after using chemical; never bring food, drink, or smoking materials into vicinity of chemicals. Barrier creams may also be useful in protecting exposed skin surfaces. | | | | |

JET FUELFormula varies with grade (may be C₅ through C₁₆)

CAS: 8008-20-6

**IDENTIFICATION AND TYPICAL USES**

Jet fuel is a clear or colorless, oily liquid with a strong, characteristic, petroleum odor. It is used primarily as a fuel for rocket engines and high performance jet aircraft.

RISK ASSESSMENT: HEALTH***General Assessment***

Jet fuel is considered moderately toxic by *inhalation* of its vapors and by *ingestion* of the liquid. Skin contact will also cause localized damage at site of contact, but dermal absorption through intact skin has not been reported. Jet fuel is not reported to be a carcinogenic, mutagenic, or teratogenic compound. However, kerosene, a close derivative, is suspected to cause cancer in animals, with mutation data also being reported.

Inhalation of the jet fuel vapors can cause mild to severe irritation of the eyes, nose, throat, and respiratory tract mucosa. Systemic effects include headache, drowsiness, burning sensation in the chest, nausea, weakness, restlessness, incoordination, and other effects of central nervous system depression such as staggering gait, slurred speech, and mental confusion. High exposures can lead to a feeling of suffocation, coma, and death due to respiratory arrest. Pulmonary edema (fluid in the lungs) can develop approximately 24 to 48 hours after exposure. This is a medical emergency and can also be fatal. There may be coughing, bloody sputum, chest pain, and congestion.

Skin contact may cause irritation producing erythema (redness), burning, and, in severe cases, edema and even blistering. Contact dermatitis is possible, as is secondary infection. Eye contact can cause irritation of the conjunctiva with redness, swelling, tearing, and localized inflammation of eye tissues.

Ingestion may cause nausea, vomiting, headaches, dizziness, gastrointestinal irritation, somnolence, hallucinations and distorted perceptions, coughing, drunkenness, fever, confusion, and diarrhea. If vom-

iting occurs, aspiration of the liquid into the lungs can cause choking, difficulty breathing or shortness of breath (dyspnea), tachypnea (rapid respiration), tachycardia (rapid heartbeat), fever, pneumonitis, and even pulmonary hemorrhage (bleeding in the lungs).

☠ *Acute Health Effects*

The following acute (short-term) health effects may occur immediately or shortly after exposure to jet fuel:

Skin: Irritation with potential for redness, blistering, and burning.

Eye: Severe irritation, conjunctivitis, redness, possible pain, and visual disturbances.

Lung: Nose, throat, and respiratory tract irritation causing difficulty in breathing, and possible pulmonary effects if liquid enters the lungs.

CNS: Inebriation, dizziness, stupor, hallucinations, slurred speech, mental confusion, loss of consciousness, and possible convulsions.

Other: Ingestion can cause serious nervous system effects and possible injury to the lungs should any vomitus be aspirated into the lungs. Other organs that may be damaged by exposure include the liver, kidney, pancreas, and spleen.

☘ *Chronic Health Effects*

The following chronic (long-term) health effects may occur at some time after exposure to jet fuel and can last for months or even years:

Cancer Hazards: According to information presented in the references, jet fuel has not been shown to cause cancer in test animal studies. Kerosene, a close derivative, has been shown to cause cancer in test animals. Its ability to cause cancer in humans is considered to be at least equal to that of animals. It is not known if jet fuel will have this effect on humans.

Reproductive Hazard: There is no evidence in the references to indicate that exposure to jet fuel causes any adverse effects to reproduction.

Other Chronic Effects: Chronic inhalation of hydrocarbon vapors can lead to neurological impairment. Repeated skin contact causes blistering, drying, cracking, and possible secondary infections and contact dermatitis.

🕒 **Recommended Risk-Reduction Measures**

Personnel should avoid direct contact with or exposure to jet fuel. Occupational poisoning occurs most commonly by inhalation. Substitution may not always be a viable option with jet fuel since its use is often as a substitute for even more toxic or flammable compounds. However, a less toxic material or compound should be used in place of jet fuel whenever possible. If substitution is not possible, *engineering controls* are the most effective method of reducing exposures. The best protection is to enclose operations and/or provide local exhaust ventilation at the site of jet fuel release. While not always operationally feasible, isolating operations can also reduce exposure. Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around jet fuel. No exposure levels have been established for jet fuel. However, this does not mean that exposure is without risk. An MSHA/NIOSH-approved air-purifying respirator with an organic vapor cartridge, a supplied-air respirator operated in continuous flow mode, or a self-contained breathing apparatus (SCBA) with full facepiece operated in pressure demand are the appropriate methods of respiratory protection when exposure to jet fuel is anticipated. If a full facepiece is not available, then chemical goggles should be worn to protect the eyes. A face shield should also be considered. To prevent hand and skin exposures, protective gloves should be used. Glove manufacturers should be contacted and permeation studies obtained *before* final glove selections are made.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with jet fuel.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where jet fuel is used or stored.

Before beginning employment and at regular times thereafter, the following recommended medical tests should be considered:

☑ Lung function tests (establish baseline).

If symptoms occur or overexposure is suspected, the following additional tests are suggested:

☑ Lung function tests (compare to baseline).

☑ Consider chest X-ray following acute overexposure (may be negative if taken immediately after exposure due to delayed onset of pulmonary edema).

☑ Liver and kidney function tests.

Any evaluation should include a careful history of past and present symptoms with an examination. Medical tests that simply look for existing damage are not a substitute for controlling exposures. Also, since smoking can cause heart disease, emphysema, lung cancer, and other respiratory disorders, smokers exposed to jet fuel may experience symptoms more rapidly and more pronounced than non-smokers under the same conditions of exposure. Prudent risk management requires careful consideration of *all* possible factors that may be causing the appearance of exposure symptoms in the workplace.

Other methods to reduce exposure include:

☑ Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not used, respiratory protection should be mandatory.

☑ Always ensure that proper protective clothing is worn when using chemical substances and that personnel are trained in its use, care, and maintenance.

☑ Wash thoroughly immediately after exposure to jet fuel and at the end of the work shift or before eating, drinking, or smoking.

☑ Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of jet fuel should be communicated to all exposed workers.

☑ Eye wash stations should be provided in the immediate work area for emergency use. If there is a possibility of skin exposure to jet fuel, emergency shower facilities should also be provided.

☑ Workers whose clothing has been contaminated by jet fuel should change into clean clothes be-

fore leaving work. Contaminated work clothing should be laundered only by individuals who have been informed of the hazards of exposure to jet fuel.

- ☑ Where possible, automatically transfer liquids containing jet fuel from drums or other containers to process containers. Always ground and bond all containers and equipment. Use non-sparking tools.

RISK ASSESSMENT: ENVIRONMENT

General Assessment

The environment is at risk of exposure during transportation, storage, disposal, or destruction of jet fuel. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance. Accidental spills, large or small, can result in contamination of the surrounding environmental mediums (water, soil, and air).

Jet fuel is a Class II combustible liquid (per OSHA 29 CFR 1910.106). It can present a dangerous fire hazard and moderate explosion hazard when exposed to heat or flame. It is incompatible with commonly encountered oxidizers and caution is always required in handling, storage, transportation, and disposal of jet fuel. Emergency responders should be made aware of the presence of jet fuel at any emergency response situation.

Jet fuel can enter the environment from industrial effluents and from spills.

☠ Acute Ecological Effects

Acute (short-term) toxic effects may include the death of animals, birds, or fish and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to jet fuel. Jet fuel has high acute toxicity to aquatic life. It can cause death in plants and roots and membrane damage in leaves of various agricultural crops. Insufficient data are available to evaluate the short-term effects of jet fuel on birds or land animals.

☪ Chronic Ecological Effects

Chronic (long-term) toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals. Jet fuel has high chronic toxicity to aquatic life. Insufficient data are available

to evaluate or predict the long-term effects of jet fuel to plants, birds, or terrestrial animals.

💧 Water Solubility

Jet fuel is not soluble in water. Concentrations of 1 milligram will not mix with a liter of water.

⌚ Persistence in the Environment

Jet fuel is slightly persistent in water, with a half-life of between 2 to 20 days. The half-life of a pollutant is the amount of time it takes for one half of the chemical to be degraded. About 99.5% of jet fuel will eventually end up in air; the rest will end up in water.

🐟 Bioaccumulation in Aquatic Organisms

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans.

The concentration of jet fuel found in fish tissues is expected to be somewhat higher than the average concentration of jet fuel in the water from which the fish was taken.

🛡 Recommended Risk-Reduction Measures

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in a leak or spill of jet fuel into the environment. Labels on all containers, trucks, and rail cars must meet DOT requirements and accurately reflect their contents to enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of jet fuel should be segregated from other chemicals and materials to minimize the risk of cross-contamination. Facilities should be designed to meet explosion-proof requirements.

If a spill or leak to the environment has occurred, fire department, emergency response and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those trained in proper spill containment procedures using non-sparking tools. Contaminated soils should be removed for incineration and replaced with clean soil. If jet fuel should contact the water table, aquifer, or navigable waterway, time is of the essence. It is not soluble and total remediation may be possible. In general, jet fuel will float on the surface and may be

captured if response actions are prompt. The local and/or state emergency response authorities must be notified. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of jet fuel.

If jet fuel is spilled or leaked, the following specific steps are recommended:

- ☑ Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened for normal work.
- ☑ Absorb liquids in vermiculite, sand, earth, or similar material and deposit in sealed drum. Use non-sparking tools during cleanup procedures.
- ☑ Ventilate area of spill or leak. Container should be removed to safer area if it can be done without increasing the risk.
- ☑ Use water spray to knock down vapors.
- ☑ It may be necessary to dispose of jet fuel as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving jet fuel can present a serious threat to business operations. The loss or damage of equipment or facilities can significantly affect fiscal viability. Lawsuits that may result from personnel illness, injury/death, public exposures, and/or environmental contamination will require a serious expenditure of resources. Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business.

🔊 *Recommended Risk-Reduction Measures*

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures for responding to chemical incidents. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

Synonyms

Chlordecone; GC-1189; ENT 16391; Merex; decachlorooctahydro-kepone-2-one; decachlorooctahydro-1,3,4-metheno-2H-cyclobuta(cd)-pentalen-2-one.

SECTION II - HAZARDOUS INGREDIENTS AND IDENTITY INFORMATION

| Hazardous Components (specific identity) | OSHA Exposure Criteria | NIOSH Exposure Criteria | Immediately Dangerous to Life and Health (IDLH) | ACGIH Exposure Criteria |
|--|---|---|---|---|
| Kepone | PEL: Not Established STEL: Not Established | REL (ceiling): 0.001 mg/m³ (15 minute) STEL: Not Applicable | Not Determined | TLV: Not Established STEL: Not Established |

SECTION III - PHYSICAL AND CHEMICAL CHARACTERISTICS

| | |
|---|---|
| Boiling Point Sublimes | Specific Gravity (H ₂ O = 1) Not Found |
| Vapor Pressure (mm Hg) <3 x 10⁻⁷ at 77°F (25°C) | Molecular Weight 490.6 |
| Vapor Density (Air = 1) Not Found | Melting Point 662°F (350°C) |

Solubility

Slightly soluble in water (0.5% at 212°F). Soluble in acetic acid, alcohols, ketones, and acetone.

Appearance and Odor

Tan to white crystalline, odorless solid.

SECTION IV - FIRE AND EXPLOSION HAZARD DATA

| | |
|---|--|
| Flash Point (method used) Not Determined | Explosive Limits in Air % by Volume LEL: Not Determined UEL: Not Determined |
| NFPA Classification Non-Combustible Solid | Autoignition Temperature Not Determined |

Extinguishing Media

Use agent suitable to surrounding area. Kepone does not burn.

Special Fire Fighting Procedures

Poisonous gases may be produced in fire; wear full protective clothing and self-contained breathing apparatus (SCBA). Move containers from fire area if it can be done safely. Use water spray to cool fire-exposed containers. Do not release runoff from fire control measures to sewers or waterways; dike far ahead and contain for proper disposal.

Unusual Fire and Explosion Hazards

None reported.

SECTION V - REACTIVITY DATA

| | | |
|---------------------------------|----------------------------|---|
| Stability | | Conditions to Avoid Normally stable in closed containers under routine conditions of storage and handling. It readily hydrates on exposure to room temperature and humidity. Avoid contact with incompatible materials. |
| Stable X | Unstable | Incompatibility (<i>materials to avoid</i>) Incompatible with acids (nitric, sulfuric, hydrofluoric, chlorosulfonic) and acid fumes. Contact with either will produce highly toxic chloride fumes. |
| Hazardous Polymerization | | Conditions to Avoid Under normal conditions of temperature and pressure, hazardous polymerization of kepone is not expected to occur. |
| May Occur | Will Not Occur X | Hazardous Decomposition or By-products Toxic and irritating gases, smoke, and fumes are produced when kepone is involved in fire. |

SECTION VI - HEALTH HAZARD DATA

| | | | |
|--|-------------------------|--------------------------------|------------------------|
| Primary Route(s) of Entry: | Inhalation? X | Absorption (skin)? X | Ingestion? X |
| Health Hazards | | | |
| INHALATION: Causes central nervous system, liver, and kidney damage with symptoms of headache, tremors, ataxia, skin changes, hyperexcitability, hyperactivity, muscle spasms, visual disturbances, chest pain, testicular atrophy, low sperm count, estrogenic effects, breast enlargements, sterility, liver lesions, and cancer. | | | |
| ABSORPTION: Headache, dizziness, nausea, vomiting, tremor, ataxia, convulsions, CNS depression, respiratory failure, and may cause cardiac irregularities. May cause skin erythema. | | | |
| INGESTION: May cause, nausea, vomiting, muscle twitching, coma, and similar effects of inhalation including liver and CNS effects and liver damage. | | | |

| | | | | |

|--|--|--|------------------------------|---|

Medical Conditions Generally Aggravated by Exposure
None Reported.

Emergency and First-aid Procedures
Eye contact: Flush immediately with water for 15 minutes (minimum); seek medical attention. **Skin contact:** Remove all contaminated clothing. Immediately wash area with large amounts of soap and water. Seek medical assistance. For **inhalation:** Remove the person from exposure. Provide respiratory assistance and CPR. Transfer to medical facility. If **swallowed:** If victim is conscious, give large amounts of milk or water and induce vomiting. Never attempt to give an unconscious or convulsing person anything by mouth. **DOCTOR:** Suggest gastric lavage and saline cathartic.

SECTION VII - PRECAUTIONS FOR SAFE HANDLING AND USE

Steps to be Taken in Case Material is Released or Spilled
Collect solid materials using a vacuum equipped with a HEPA filter. Damp mop residue. Do NOT dry sweep (generates airborne dusts). Ventilate area. Restrict those not involved in cleanup from entering area. Notify appropriate authorities, if applicable.

Preferred Waste Disposal Method
Mix with a combustible solvent and burn in a chemical incinerator with an afterburner and scrubber.

Precautions to be Taken in Handling and Storage
Do not store kepone in the presence of incompatible chemicals or materials. Store in tightly closed containers in a cool, dark, well-ventilated area. Personnel working with kepone should be trained on its proper handling and storage prior to being assigned to such responsibilities.

Other Precautions and Warnings
Manufacture and use are prohibited in the United States. Bulk storage is not recommended.

SECTION VIII - CONTROL MEASURES AND PERSONAL PROTECTIVE EQUIPMENT

Respiratory Protection (*specify type*)
Exposure levels are low and compound is carcinogenic. At any exposure level use a supplied-air respirator with full facepiece operated in pressure demand mode or a self-contained breathing apparatus (SCBA) with full facepiece operated in pressure demand or other positive pressure mode.

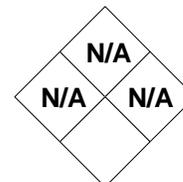

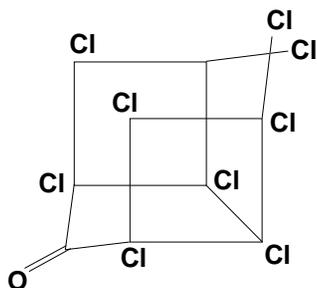

Ventilation
Local exhaust or general mechanical systems recommended.

| | | |
|---|---|--|
| Protective Gloves Protective Material | Eye Protection Chemical/Dust Goggles or Face Mask | Other Protective Clothing Protective Apron |
|---|---|--|

Work/Hygiene Practices
Always wash hands thoroughly after using chemical; never bring food, drink, or smoking materials into vicinity of chemicals.

KEPONEC₁₀Cl₁₀O

CAS: 143-50-0

**IDENTIFICATION AND TYPICAL USES**

Kepone is a tan to white, crystalline, odorless solid. It was used as an insecticide and fungicide. However, its manufacture and use is now prohibited and its registration by the U.S. Environmental Protection Agency has been suspended.

RISK ASSESSMENT: HEALTH**General Assessment**

Kepone is a deadly human poison by all routes of exposure (*ingestion, inhalation, and dermal absorption*). It is a known carcinogen in animals and is suspected to have the same effect on humans. Experimental teratogenic data have been reported along with adverse effects on the reproductive system. Mutagenic data have also been confirmed. Its primary systemic effect is damage or injury to the central nervous system and/or the liver and kidneys.

Exposure by all routes can cause depression of the central nervous system (CNS) with symptoms of headache, vertigo, blurred vision, lachrymation, salivation, sweating, muscular weakness and ataxia with spasms, dyspnea, diarrhea, abdominal cramps, vomiting, tremors, skin changes, hyperexcitability, hyperactivity, anxiety, irritability, memory disturbances, stuttering and slurred speech, abnormal gait, testicular atrophy, low sperm count, estrogenic effects, sterility, breast enlargement, fetal toxicity, anemia, liver lesions with hepatocellular carcinomas and hyperplasia, brain effects, and cancer.

Skin or eye contact results in severe irritation and discomfort. Kepone may be absorbed through unbroken skin to cause toxic systemic effects up to and including liver and CNS damage.

☠ Acute Health Effects

The following acute (short-term) health effects may occur immediately or shortly after exposure to kepone:

Skin: Irritation and possible allergy. Most effect from skin contact is internal due to absorption of kepone. Symptoms include vomiting, nausea, malaise, and muscular twitching.

Eye: Possible irritation and damage if not removed immediately.

Lung: Irritation causing coughing and/or shortness of breath. Higher exposures can lead to respiratory problems.

CNS: Dizziness, headaches, nausea, vomiting, muscle jerks, convulsions, tremors, ataxia, memory disturbances, irritability, excitement, anxiety, and speech problems.

Other: Sterility, fetal toxicity, estrogenic effects, testicular atrophy, and other reproductive effects.

☘ Chronic Health Effects

The following chronic (long-term) health effects may occur at some time after exposure to kepone and can last for months or even years:

Cancer Hazards: According to the information presented in the references, kepone has been shown to cause cancer in test animals. Its ability to cause cancer in humans is considered to be at least suspect. It has also been shown to cause mutations (genetic changes).

Reproductive Hazard: Kepone is an experimental teratogen in animals causing fetal changes as well as a reproductive hazard causing testicular atrophy, estrogenic changes, breast enlargement, and sterility.

Other Chronic Effects: Repeated or long-term exposures can lead to liver, kidney, brain, and central nervous system damage.

🔑 **Recommended Risk-Reduction Measures**

Kepone is extremely toxic to humans and animals such that its use and manufacture is no longer permitted. However, some stock may exist especially in the agricultural sector and exposures are still possible. Using a less toxic compound in its place is the best way to prevent exposures. But when a less toxic chemical is not available or identified for substitution, *engineering controls* become the most effective method of reducing exposures. The best protection is to enclose operations and/or provide local exhaust ventilation at the site of chemical release. This may not be feasible during use as an insecticide outdoors, but it may be possible during handling and storage of kepone. While not always operationally feasible, isolating operations can also reduce exposure.

Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around kepone. The NIOSH REL is extremely low (0.001 mg/m³) and difficult to accurately monitor. For any exposure to a known carcinogen, a supplied-air respirator or a self-contained breathing apparatus (SCBA) with full facepiece operated in pressure demand are the recommended respiratory protection methods of choice. If a full facepiece is not available, then chemical goggles should be worn to protect the eyes. Whenever a chemical splash hazard exists a face shield and protective apron should be worn. To prevent hand and skin exposures, rubber gloves should be used.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with kepone.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where kepone is used or stored.

If symptoms develop or overexposure is suspected, the following medical tests may be useful:

- ☑ Liver and kidney function tests.
- ☑ Evaluation by a qualified neurologist with careful evaluation of exposure history and administration of special tests.

Any evaluation should include a careful medical history of past and present symptoms with an examination. However, medical tests that evaluate existing damage are not a substitute for controlling exposure.

Other methods to reduce exposure include:

- ☑ Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not used, respiratory protection should be mandatory.
- ☑ Always ensure that proper protective clothing is worn when using chemical substances.
- ☑ Wash thoroughly immediately after exposure to kepone and at the end of the work shift or before eating, drinking, or smoking.
- ☑ Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of kepone should be communicated to all exposed or potentially exposed workers.
- ☑ Eye wash stations should be provided in work areas. If the potential for whole body exposure exists, then safety showers should also be provided.

RISK ASSESSMENT: ENVIRONMENT

General Assessment

The environment is at risk of exposure during intended use, transportation, storage, disposal, or destruction of kepone. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance. Accidental spills, large or small, can result in fire, explosion, and possible contamination of the surrounding environmental mediums (water, soil, and air).

Kepone is considered a non-combustible solid. However, it is reactive in contact with acid or acid fumes and will produce toxic chloride fumes. It may also form poisonous phosgene gas on exposure to heat. These characteristics require special consideration during any emergency situation involving a leak or spill of kepone or kepone mixtures. Should kepone ever come into contact with incompatible substances either during use, transportation, or storage, violent reaction can occur.

Kepone can enter the environment through its normal, intended use as an insecticide and fungicide,

and through industrial discharges, urban runoff, and spills.

☠ *Acute Ecological Effects*

Acute (short-term) toxic effects may include the death of animals, birds, or fish and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to kepone.

Kepone has high acute toxicity to aquatic life, birds, and land animals. Insufficient data are available to evaluate or predict the short-term effects of kepone to plant life.

🕒 *Chronic Ecological Effects*

Chronic toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals.

Kepone has high chronic toxicity to aquatic life. Insufficient data are available to evaluate or predict the long-term effects of kepone to plants, birds, or land animals.

💧 *Water Solubility*

Kepone is very slightly soluble in hot water. Concentrations up to 100 milligrams will mix with a liter of hot water.

🕒 *Persistence in the Environment*

Kepone is highly persistent in water, with a half-greater than 200 days. The half-life of a pollutant is the amount of time it takes for one-half of the chemical to be degraded.

🐟 *Bioaccumulation in Aquatic Organisms*

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans.

The concentration of kepone found in fish tissues is expected to be much higher than the average concentration of kepone in the water from which the fish was taken.

🛡️ *Recommended Risk-Reduction Measures*

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in a leak or

spill to the environment. The correct use of labeling on all containers, trucks, and rail cars will enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of kepone should be segregated from incompatible chemicals to minimize the risk of cross-contamination or contact.

If a spill or leak to the environment has occurred, fire department, emergency response and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those trained in proper spill containment procedures. Contaminated soils should be removed for incineration and replaced with clean soil. If kepone should contact the water table, aquifer, or navigable waterway, remediation activities should be prompt to ensure protection of aquatic sediments. When such spills occur, the local and/or state emergency response authorities must be notified. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of kepone. The correct disposal method is to mix kepone with a combustible solvent and burn it in a chemical incinerator equipped with an afterburner and scrubber.

If kepone is spilled or leaked, the following specific steps are recommended:

- ☑ Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened for normal work.
- ☑ Collect solid materials in safest manner possible and deposit in sealed drums. Do NOT dry sweep (creates airborne dusts). Use a vacuum equipped with a high-efficiency particulate air (HEPA) filter instead. Damp mop residue and collect for disposal. Avoid unprotected contact with kepone.
- ☑ It may be necessary to dispose of kepone as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving kepone can present a significant threat to business operations. The loss or damage of equipment or facilities can significantly

affect fiscal viability. Lawsuits that may result from personnel injury/death, public exposures, and/or environmental contamination will also require a serious expenditure of resources. Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business. Always remember that anytime the terms "cancer," "carcinogen," or "reproductive hazard" are used, public hysteria, emotion, and ignorance can run equally high. This must be carefully considered whenever developing or implementing public relation policy.

🕒 Recommended Risk-Reduction Measures

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures dealing with safety or emergency response. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

| Primary Route(s) of Entry: | | Inhalation? X | Absorption (skin/eye)? | Ingestion? X |
| Health Hazards INHALATION: Symptoms include irritation of the nose, throat, and mucosa of the respiratory tract with headache and drowsiness. High concentrations can cause feeling of suffocation, coma, and death (respiratory arrest). Chronic exposures can lead to neurological impairment. SKIN & EYES: Irritation with drying, cracking, redness, blistering (prolonged contact). May lead to contact dermatitis and secondary infection. INGESTION: May cause nausea, vomiting, headache and gastrointestinal irritation. Aspiration of vomit into the lungs can cause serious pneumonitis and even pulmonary hemorrhage. | | | | |
| Carcinogenicity Suspected Human Suspected Animal | NTP Listed? No | IARC Cancer Review Group? Group 2A | OSHA Regulated? No | Target Organs? Eyes, skin, respiratory sys., blood, CNS, kidneys. |
| Medical Conditions Generally Aggravated by Exposure None identified. | | | | |
| Emergency and First-aid Procedures Eye contact: Do not allow victim to keep eyes tightly shut. Flush immediately with water for 15 minutes (minimum); seek medical attention. Skin contact: Remove all contaminated clothing, including shoes. Immediately wash area with flooding amounts of soap and water. Seek medical attention if blisters develop. For inhalation: Remove the person from exposure. Provide respiratory assistance and CPR. Transfer to medical facility. If swallowed: Seek medical attention immediately. Give conscious person milk or water to drink. Do NOT induce vomiting (possible aspiration of vomitus/chemical into the lungs). | | | | |
| SECTION VII - PRECAUTIONS FOR SAFE HANDLING AND USE | | | | |
| Steps to be Taken in Case Material is Released or Spilled Remove all ignition sources. Wear SCBA respiratory protection. Restrict those not wearing protective equipment and who are not involved in cleanup from entering area. Avoid skin contact. Stop leak if it can be done without risk. Provide maximum explosion-proof ventilation. Absorb with vermiculite or other similar material and deposit in sealed containers. Use non-sparking tools during cleanup. | | | | |
| Preferred Waste Disposal Method No Citation. | | | | |
| Precautions to be Taken in Handling and Storage Store in tightly closed containers in cool, well-ventilated location. Keep away from sources of heat. | | | | |
| Other Precautions and Warnings Sources of ignition such (open flame or smoking), are prohibited where kerosene is used or stored. Metal containers should be bonded and grounded during transfer operations. Bulk storage not recommended. | | | | |
| SECTION VIII - CONTROL MEASURES AND PERSONAL PROTECTIVE EQUIPMENT | | | | |
| Respiratory Protection (<i>specify type</i>) Use an MSHA/NIOSH-approved air-purifying organic vapor respirator, a powered air purifying respirator, or a self-contained breathing apparatus (SCBA) with full facepiece operated in positive pressure mode. | | | | |
| Ventilation Local exhaust (preferred) at site of chemical work or general ventilation. | | | | |
| Protective Gloves Impervious Material | | Eye Protection Chemical Goggles or Face Mask | | Other Protective Clothing Protective Apron if Splash is Likely |
| Work/Hygiene Practices Always wash hands thoroughly after using chemical; never bring food, drink, or smoking materials into vicinity of chemicals. Barrier creams may also be useful in protecting exposed skin surfaces. | | | | |

KEROSENEFormula varies with grade (may be C₁₀ through C₁₆)

CAS: 8008-20-6

**IDENTIFICATION AND TYPICAL USES**

Kerosene is a clear or colorless to slightly yellow, oily liquid with a strong, characteristic, petroleum odor. It is used primarily as a fuel for rocket engines, kerosene lamps, flares, portable cooking stoves, diesel engines, and tractors. It is also used as an industrial solvent and degreasing agent, a cleaner, a mold-releasing agent, a solvent for asphalt coatings, enamels, paints, polishes, thinners, and varnishes. It is sometimes used by veterinarians for decontamination.

RISK ASSESSMENT: HEALTH**General Assessment**

Kerosene is considered moderately toxic by *inhalation* of its vapors and by *ingestion* of the liquid. Skin contact will also cause localized damage at site of contact, but dermal absorption through intact skin has not been reported. It is suspected to cause cancer in animals with mutation data also being reported. Its teratogenic properties have not been documented in the references.

Inhalation of the kerosene vapors can cause mild to severe irritation of the eyes, nose, throat, and respiratory tract mucosa. Systemic effects include headache, drowsiness, burning sensation in the chest, nausea, weakness, restlessness, incoordination, and other effects of central nervous system depression. High exposures can lead to a feeling of suffocation, coma, and death due to respiratory arrest.

Skin contact may cause irritation producing erythema (redness), burning, and, in severe cases, edema and even blistering. Contact dermatitis is possible, as is secondary infection. Eye contact can cause irritation of the conjunctiva with redness, swelling, tearing, and localized inflammation of eye tissues.

Ingestion may cause nausea, vomiting, headaches, dizziness, gastrointestinal irritation, somnolence, hallucinations and distorted perceptions, coughing, fever, drunkenness, confusion, and diarrhea. If vomiting

occurs, aspiration of the liquid into the lungs can cause choking, difficulty breathing or shortness of breath (dyspnea), tachypnea (rapid respiration), tachycardia (rapid heartbeat), fever, pneumonitis, and even pulmonary hemorrhage (bleeding in the lungs).

☠ Acute Health Effects

The following acute (short-term) health effects may occur immediately or shortly after exposure to kerosene:

Skin: Irritation with potential for redness, blistering, and burning.

Eye: Severe irritation, conjunctivitis, redness, possible pain, and visual disturbances.

Lung: Nose, throat, and respiratory tract irritation causing difficulty in breathing, possible pulmonary effects if liquid enters the lungs.

CNS: Inebriation, dizziness, stupor, hallucinations, slurred speech, mental confusion, loss of consciousness, and possible convulsions.

Other: Ingestion can cause serious nervous system effects and possible injury to the lungs should any vomitus be aspirated into the lungs.

☠ Chronic Health Effects

The following chronic (long-term) health effects may occur at some time after exposure to kerosene and can last for months or even years:

Cancer Hazards: Kerosene is a suspected carcinogen in animal studies. Its ability to cause cancer in humans is considered to be at least equal to that of animals.

Reproductive Hazard: There is no evidence in the references to indicate that exposure to kerosene causes any adverse effects to reproduction.

Other Chronic Effects: Chronic inhalation of hydrocarbon vapors can lead to neurological impairment.

Repeated skin contact causes blistering, drying, cracking, and possible secondary infections and contact dermatitis.

🕒 **Recommended Risk-Reduction Measures**

Personnel should avoid direct contact with or exposure to kerosene. Occupational poisoning occurs most commonly by inhalation. Substitution may not always be a viable option with kerosene since its use is often as a substitute for even more toxic or flammable compounds. However, a less toxic material or compound should be used in place of kerosene whenever possible. If substitution is not possible, *engineering controls* are the most effective method of reducing exposures. The best protection is to enclose operations and/or provide local exhaust ventilation at the site of kerosene release. While not always operationally feasible, isolating operations can also reduce exposure. Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around kerosene. An MSHA/NIOSH-approved air-purifying respirator with an organic vapor cartridge, a supplied-air respirator operated in continuous flow mode, or a self-contained breathing apparatus (SCBA) with full facepiece operated in pressure demand are the appropriate methods of respiratory protection when exposure to kerosene is anticipated. If a full facepiece is not available, then chemical goggles should be worn to protect the eyes. A face shield should also be considered. To prevent hand and skin exposures, protective gloves should be used. Glove manufacturers should be contacted and permeation studies obtained *before* final glove selections are made.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with kerosene.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where kerosene is used or stored.

Before beginning employment and at regular times thereafter, the following recommended medical tests should be considered:

- Lung function tests (establish baseline).

If symptoms occur or overexposure is suspected, the following additional tests are suggested:

- Lung function tests (compare to baseline).

- Liver and kidney function tests.

Any evaluation should include a careful history of past and present symptoms with an examination. Medical tests that simply look for existing damage are not a substitute for controlling exposures.

Other methods to reduce exposure include:

- Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not used, respiratory protection should be mandatory.
- Always ensure that proper protective clothing is worn when using chemical substances.
- Wash thoroughly immediately after exposure to kerosene and at the end of the work shift or before eating, drinking, or smoking.
- Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of kerosene should be communicated to all exposed workers.
- Eye wash stations should be provided in the immediate work area for emergency use. If there is a possibility of skin exposure to kerosene, emergency shower facilities should also be provided.
- Workers whose clothing has been contaminated by kerosene should change into clean clothes before leaving work. Contaminated work clothing should be laundered only by individuals who have been informed of the hazards of exposure to kerosene.
- Where possible, automatically transfer liquids containing kerosene from drums or other containers to process containers. Always ground and bond all containers and equipment. Use non-sparking tools.

RISK ASSESSMENT: ENVIRONMENT

General Assessment

The environment is at risk of exposure during transportation, storage, disposal, or destruction of kerosene. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance. Accidental spills, large or small, can result in contamination of the surrounding environmental mediums (water, soil, and air).

Kerosene is a Class II combustible liquid (per OSHA 29 CFR 1910.106). It can present a dangerous

fire hazard and moderate explosion hazard when exposed to heat or flame. It is incompatible with commonly encountered oxidizers and caution is always required in handling, storage, transportation, and disposal of kerosene. Emergency responders should be made aware of the presence of kerosene at any emergency response situation.

Kerosene can enter the environment from industrial effluents and from spills.

☠ *Acute Ecological Effects*

Acute (short-term) toxic effects may include the death of animals, birds, or fish and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to kerosene. Kerosene has high acute toxicity to aquatic life. It can cause death in plants and roots and membrane damage in leaves of various agricultural crops. Insufficient data are available to evaluate the short-term effects of kerosene on birds or land animals.

🕒 *Chronic Ecological Effects*

Chronic (long-term) toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals. Kerosene has high chronic toxicity to aquatic life. Insufficient data are available to evaluate or predict the long-term effects of kerosene to plants, birds, or terrestrial animals.

💧 *Water Solubility*

Kerosene is not soluble in water. Concentrations of 1 milligram will not mix with a liter of water.

🕒 *Persistence in the Environment*

Kerosene is slightly persistent in water, with a half-life of between 2 to 20 days. The half-life of a pollutant is the amount of time it takes for one half of the chemical to be degraded. About 99.5% of kerosene will eventually end up in air; the rest will end up in water.

🐟 *Bioaccumulation in Aquatic Organisms*

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans.

The concentration of kerosene found in fish tissues is expected to be somewhat higher than the average concentration of kerosene in the water from which the fish was taken.

🛑 *Recommended Risk-Reduction Measures*

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in a leak or spill of kerosene into the environment. Labels on all containers, trucks, and rail cars must meet DOT requirements and accurately reflect their contents to enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of kerosene should be segregated from other chemicals and materials to minimize the risk of cross-contamination. Facilities should be designed to meet explosion-proof requirements.

If a spill or leak to the environment has occurred, fire department, emergency response and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those trained in proper spill containment procedures using non-sparking tools. Contaminated soils should be removed for incineration and replaced with clean soil. If kerosene should contact the water table, aquifer, or navigable waterway, time is of the essence. It is not soluble and total remediation may be possible. In general, kerosene will float on the surface and may be captured if response actions are prompt. The local and/or state emergency response authorities must be notified. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of kerosene.

If kerosene is spilled or leaked, the following specific steps are recommended:

- Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened for normal work.
- Absorb liquids in vermiculite, sand, earth, or similar material and deposit in sealed drum. Use non-sparking tools during cleanup procedures.
- Ventilate area of spill or leak. Container should be removed to safer area if it can be done without increasing the risk.
- Use water spray to knock down vapors.
- It may be necessary to dispose of kerosene as a hazardous waste. The responsible state agency or the regional office of the federal Environ-

mental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving kerosene can present a serious threat to business operations. The loss or damage of equipment or facilities can significantly affect fiscal viability. Lawsuits that may result from personnel illness, injury/death, public exposures, and/or environmental contamination will require a serious expenditure of resources.

Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business. Always remember that anytime the terms "cancer," or "carcinogen" are used, public emotion, hysteria, and ignorance can run equally high. This must be carefully considered when developing or implementing any public relations policies.

Recommended Risk-Reduction Measures

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures for responding to chemical incidents. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

Extinguishing Media
Stop flow of gas before attempting to extinguish fire. Use water spray to knock down vapors.
Special Fire Fighting Procedures
Extremely poisonous gas. Wear full protective clothing and self-contained breathing apparatus (SCBA). Heat will build pressure and may rupture closed storage containers. Fight fire from an explosion-proof distance if possible. Use unmanned equipment to control fires. Fire cannot be stopped until gas release is stopped first. Keep fire-exposed containers cool with water spray.
Unusual Fire and Explosion Hazards
Ketene will react and decompose to acetic acid in contact with water. Avoid using water as an extinguishing agent until gas flow can be stopped.

| SECTION V - REACTIVITY DATA | | | | |
|--|--|--|--|--|
| Stability | | Conditions to Avoid Ketene is normally stable in closed containers under routine conditions of handling or storage. Avoid contact with incompatible materials, heat, or ignition sources. | | |
| Stable X | Unstable | Incompatibility (<i>materials to avoid</i>) Reacts with water to form acetic acid, decomposes in alcohols, ammonia, and reacts with hydrogen peroxide to form explosive diacetyl peroxide. | | |
| Hazardous Polymerization | | Conditions to Avoid Ketene readily polymerizes under normal conditions of temperature and pressure. | | |
| May Occur X | Will Not Occur | Hazardous Decomposition or By-products When heated to decomposition, ketene emits acrid, irritating smoke and fumes, including toxic gases such as carbon monoxide. | | |
| SECTION VI - HEALTH HAZARD DATA | | | | |
| Primary Route(s) of Entry: | | Inhalation? X | Absorption (skin)? | Ingestion? |
| Health Hazards INHALATION: Extremely irritating to the eyes, nose, throat, and especially the upper respiratory tract. Can cause difficulty in breathing, cough, and pulmonary edema (fluid in the lungs). SKIN & EYES: Skin contact can result in irritating rash or burning feeling. Can cause severe eye burns leading to permanent damage. Serious damage occurs as a result of frostbite. INGESTION: Not likely, ketene is a gas. | | | | |
| Carcinogenicity Unknown Human Unknown Animal | NTP Listed? No | IARC Cancer Review Group? No | OSHA Regulated? 29 CFR 1910.1000 (Table Z-1) | Target Organs? Respiratory system; skin; eyes. |
| Medical Conditions Generally Aggravated by Exposure Respiratory function impairments (asthma, etc.) may be aggravated by exposure. | | | | |
| Emergency and First-aid Procedures Eye contact: Immediately flush with large amounts of warm, tepid water for 15 minutes (minimum); occasionally lifting eyelids; seek medical attention immediately. Skin contact: Remove all contaminated clothing. Immediately wash area with large amounts of warm, tepid water. Treat for frostbite. Do NOT rub affected area and do NOT attempt to warm skin using hot, blown air. For inhalation: Remove the person from exposure. Provide respiratory assistance and CPR. Transfer promptly to medical facility. Observe 48 for hours for lung effects. If swallowed: Unlikely to occur (ketene is a gas). | | | | |
| SECTION VII - PRECAUTIONS FOR SAFE HANDLING AND USE | | | | |
| Steps to be Taken in Case Material is Released or Spilled Remove all ignition sources. Restrict persons not wearing protective equipment from entering area of gas leak. Ventilate area. Stop flow of leak. Use water spray to knock down vapors and protect personnel who are attempting to stop leak (use caution since ketene will react with water to form acetic acid). | | | | |
| Preferred Waste Disposal Method No citation. | | | | |
| Precautions to be Taken in Handling and Storage Ketene is a highly flammable and poisonous gas. Do not store with incompatible chemicals since violent reactions can occur. Store in tightly closed containers in a cool, dark, well-ventilated area away from fire, sparks, and flame. Use non-sparking tools on containers. Ground and bond metal containers during transfer operations. Use external or detached facility storage if possible. | | | | |
| Other Precautions and Warnings Bulk storage of ketene is not recommended. Containers may explode in fire or under conditions of extreme heat (do not store outdoors or in direct sunlight). | | | | |
| SECTION VIII - CONTROL MEASURES AND PERSONAL PROTECTIVE EQUIPMENT | | | | |
| Respiratory Protection (<i>specify type</i>) Exposure levels are extremely low (0.5 ppm) and ketene is extremely irritating. Use a supplied-air respiratory operated in positive pressure mode or a self-contained breathing apparatus (SCBA) with full face-piece and pressure demand or other positive pressure mode. | | | | |
| Ventilation Local exhaust or general mechanical systems recommended. | | | | |
| Protective Gloves Impervious, Thermal Gloves | Eye Protection Chemical Goggles and/or Face Mask | Other Protective Clothing Protective Apron | | |
| Work/Hygiene Practices Always wash hands thoroughly after using chemical; never bring food, drink, or smoking materials into vicinity of chemicals. | | | | |

KETENE

CAS: 463-51-4

**IDENTIFICATION AND TYPICAL USES**

Ketene is a colorless gas with a penetrating, disagreeable, sharp odor. It is used as an acetylating agent in the production of cellulose acetate, aspirin, acetic anhydride, and in various organic syntheses. It generally reacts with ammonia to produce acetamide. It is also a starting point for making various commercial products such as acetic anhydride and acetate esters.

RISK ASSESSMENT: HEALTH***General Assessment***

Ketene is a highly toxic and extremely irritating gas. As a gas, it can enter the body primarily through *inhalation*. Skin contact with the compressed gas can cause serious, frostbite-type burns and damage, but dermal absorption has not been reported. There are no reports of carcinogenic, mutagenic, or teratogenic effects occurring as a result of exposure to ketene.

Inhalation will cause immediate and possibly severe irritation of the eyes, nose, throat, and upper respiratory tract. Concentrations of only 10 to 15 ppm for several minutes can injure the respiratory tract and lungs leading to a dangerous buildup of fluid in the lungs (pulmonary edema) which can be fatal. Symptoms of headache, cough, dizziness, congestion, and tightness in chest may be delayed up to 48 hours, thereby causing a false sense of security with regard to health exposure risk.

Skin or eye contact will cause irritation, rash, burns, and possible tissue destruction (frostbite) as a result of the cryogenic properties of compressed ketene.

☠ Acute Health Effects

The following acute (short-term) health effects may occur immediately or shortly after exposure to ketene:

Skin: Irritation/rash or burning sensation, frostbite, and cryogenic burns on contact.

Eye: Burns which can lead to permanent damage.

Lung: Irritation causing coughing and/or shortness of breath leading to pulmonary edema and death.

☠* Chronic Health Effects

The following chronic (long-term) health effects may occur at some time after exposure to ketene and can last for months or even years:

Cancer Hazards: According to information presented in the references, exposure to ketene does not currently lead to carcinogenic or mutagenic effects.

Reproductive Hazards: There are no reports in the references to support any claims of reproductive hazards resulting from exposure to ketene gas.

Other Chronic Effects: Human data on chronic exposures are limited in the references. However, animal studies have shown an increase in emphysema and pulmonary fibrosis resulting from prolonged or repeated exposure to low levels of ketene gas.

🛡 Recommended Risk-Reduction Measures

Personnel should avoid direct contact with ketene. It is extremely toxic and can damage the respiratory system. Unless a less toxic chemical can be substituted for a hazardous substance, *engineering controls* are the most effective method of reducing exposures. The best protection is to enclose operations and/or provide local exhaust ventilation at the site of chemical release. While not always operationally feasible, isolating operations can also reduce exposure. Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with ketene. The exposure level is extremely low (0.5 ppm) and difficult to accurately monitor. For the best protection, use a NIOSH/MSHA-approved, full facepiece supplied-air respirator operated in continuous flow mode or a self-contained breathing apparatus (SCBA) with full facepiece operated in pressure

demand or other positive pressure mode. If a full facepiece is not available, then chemical goggles should be worn to protect the eyes. Whenever a compressed gas hazard exists, a face shield and a protective apron should be worn. To prevent hand and skin exposures, impervious, thermal protective gloves should be used. Glove manufacturers should be contacted and permeation studies obtained *before* final glove selections are made.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with ketene.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where ketene is used or stored.

If symptoms develop or overexposure is suspected, the following medical tests are recommended:

- Lung function tests.
- Consider chest X-ray following acute overexposure (may be negative if taken immediately after exposure due to delayed onset of pulmonary edema).

Also, since smoking can cause heart disease, emphysema, lung cancer, and other respiratory disorders, smokers exposed to ketene may experience symptoms more rapidly and more pronounced than non-smokers under the same conditions of exposure. Prudent risk management requires careful consideration of *all* possible factors that may be causing the appearance of exposure symptoms in the workplace.

Other methods to reduce exposure include:

- Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not used, respiratory protection should be mandatory.
- Always ensure that proper protective clothing is worn when using chemical substances.
- Wash thoroughly immediately after exposure to ketene and at the end of the work shift or before eating, drinking, or smoking. Never wear clothes contaminated with ketene home.
- Hazard warning information should be posted in the work area. As part of an on-going education and training program, all information on the health and safety hazards of ketene should be communicated to all potentially exposed workers.

RISK ASSESSMENT: ENVIRONMENT

General Assessment

The environment is at risk of exposure during transportation, storage, disposal, or destruction of ketene. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance. Accidental spills can result in fire, explosion, and possible contamination of the various environmental mediums (water, soil, and primarily air).

Ketene is considered a highly flammable gas and presents a dangerous fire and explosion hazard. It is also incompatible with a number of commodities, including water, alcohols, and ammonia. It will react with hydrogen peroxide to form explosive diacetyl peroxide. These characteristics require special consideration during any emergency involving a leak of ketene.

Ketene can enter the environment through unchecked discharge and emissions from industrial or municipal waste treatment plants, and through spills.

Acute Ecological Effects

Acute (short-term) toxic effects may include the death of animals, birds, or fish, and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to ketene.

Insufficient data are available to evaluate or predict the short-term effects of ketene on aquatic life, birds, plants, or land animals.

Chronic Ecological Effects

Chronic (long-term) toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals.

Insufficient data are available to evaluate or predict the long-term effects of ketene on aquatic life, birds, plants, or land animals.

Water Solubility

Ketene is insoluble in water. It will react and decompose to form acetic acid which is highly soluble in water. Acetic acid concentrations up to 1000 milligrams and possibly more will readily mix with a liter of water.

Persistence in the Environment

Ketene is non-persistent in water, with a half-life of less than 2 days. However, acetic acid, its decomposition product, is highly persistent in water with a half life between 20 and 200 days. The half-life of a pollutant is the amount of time it takes for one half of the chemical to be degraded.

🐟 Bioaccumulation in Aquatic Organisms

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans.

The concentration of ketene found in fish tissues is expected to be much lower than the average concentration of ketene in water from which the fish was taken. The concentration of acetic acid found in fish tissues is expected to be equal to or greater than the average concentration of acetic acid in the water from which the fish was taken.

🔧 Recommended Risk-Reduction Measures

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in a leak or spill to the environment. The correct use of DOT labeling (per the MSDS) on all containers, trucks, and rail cars will enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of ketene should be segregated from incompatible chemicals to minimize the risk of cross-contamination or contact. Buildings designated for storage should be equipped with appropriate fire protection systems (alarms, sprinklers, emergency lighting, portable extinguishers).

If a spill or leak to the environment has occurred, fire department, emergency response, and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those trained in proper spill containment procedures using non-sparking tools. Contaminated soils should be removed for incineration and replaced with clean soil. If ketene should contact the water table, aquifer, or navigable waterway, time is of the essence. It is readily miscible in water and, therefore, total containment and remediation may not be entirely possible. When such spills occur, the local and/or state emergency response authorities must be notified. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or

disposal of ketene. If ketene is spilled or leaked, the following specific steps are recommended:

- ☑ Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened for normal work.
- ☑ Remove all ignition sources.
- ☑ Provide maximum explosion-proof ventilation in area of spill or leak.
- ☑ Stop flow of gas. If leak is from a cylinder and cannot be stopped, move cylinder to a safe location (outdoors) if it can be done without risk. Allow to vent until empty. Use water spray to knock down vapors and to protect personnel working to stop leak.
- ☑ Keep ketene out of a confined space, such as a sewer, because of the possibility of explosion (unless the sewer is designed to prevent the buildup of explosive concentrations).
- ☑ It may be necessary to dispose of ketene as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving ketene can present a significant threat to business operations. The loss or damage of equipment or facilities can significantly affect fiscal viability. Lawsuits that may result from personnel injury, public exposures, and/or environmental contamination will also require a serious expenditure of resources.

Media attention surrounding an injury, illness, or environmental damage can also result in a loss of profits and loss of current as well as future business.

🔧 Recommended Risk-Reduction Measures

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures that deal with or address safety, emergency response, or employee health issues. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

| Stability | | Conditions to Avoid Lactic acid is normally stable under routine conditions of handling and storage. Avoid contact with heat and ignition sources and incompatible materials. | | |
| Stable X | Unstable | Incompatibility (<i>materials to avoid</i>) Mixtures with nitric acid + hydrofluoric acid reacts vigorously. Corrodes some metals (steel, aluminum, cast iron, carbon steel). | | |
| Hazardous Polymerization | | Conditions to Avoid Under normal conditions of temperature and pressure, hazardous polymerization of lactic acid is not expected to occur. | | |
| May Occur | Will Not Occur X | Hazardous Decomposition or By-products When heated to decomposition, lactic acid can emit highly toxic and acrid smoke and irritating fumes, including toxic oxides of carbon. | | |
| SECTION VI - HEALTH HAZARD DATA | | | | |
| Primary Route(s) of Entry: | | Inhalation? X | Absorption (skin)? | Ingestion? X |
| Health Hazards INHALATION: Extremely irritating to the eyes, nose, throat, and respiratory system. Inhaled dusts or mists may cause coughing, bronchial irritation, and inflammation of associated mucosa. EYES & SKIN: Skin and eye contact causes irritation. Eye contact produces burns, conjunctivitis, and possible corneal abrasions. Skin contact causes burns and may cause eczema. INGESTION: Causes burns to the mouth, throat, esophagus, and stomach with nausea and vomiting, sweating, dyspnea, cyanosis, and vascular effects. | | | | |
| Carcinogenicity Unknown Human Unknown Animal | NTP Listed? No | IARC Cancer Review Group? No | OSHA Regulated? No | Target Organs? Respiratory system, eyes, skin. |
| Medical Conditions Generally Aggravated by Exposure None reported. | | | | |
| Emergency and First-aid Procedures <u>Eye contact:</u> Flush immediately with water for 15 minutes (minimum); seek medical attention. <u>Skin contact:</u> Remove all contaminated clothing. Immediately flush area with large amounts of water. For red or blistered skin, wash with soap and water. Seek medical assistance. For <u>inhalation:</u> Remove the person from exposure. Provide respiratory assistance and CPR. Transfer to medical facility. If <u>swallowed:</u> Contact poison control center. Unless advised otherwise, give 1 to 2 glasses of water or milk. Do NOT induce vomiting. Never attempt to give anything by mouth to an unconscious or convulsing person. | | | | |
| SECTION VII - PRECAUTIONS FOR SAFE HANDLING AND USE | | | | |
| Steps to be Taken in Case Material is Released or Spilled Collect powdered materials in safest manner possible. Do NOT dry sweep (generates dusts). Use a HEPA vacuum instead. Absorb solution spills in vermiculite or similar materials and deposit in sealed containers. Ventilate area of spill or leak. Restrict those not involved in cleanup from entering area. | | | | |
| Preferred Waste Disposal Method Mix with a combustible liquid and burn in a chemical incinerator with afterburner and scrubber. | | | | |
| Precautions to be Taken in Handling and Storage Avoid contact with incompatible materials, especially nitric and hydrofluoric acid. Store in tightly closed containers in cool, well-ventilated area away from heat. Protect container from damage. | | | | |
| Other Precautions and Warnings Avoid generating dusty conditions in storage areas. Do not store in aluminum, cast iron, or carbon steel containers. Keep containers tightly closed. | | | | |
| SECTION VIII - CONTROL MEASURES AND PERSONAL PROTECTIVE EQUIPMENT | | | | |
| Respiratory Protection (<i>specify type</i>) No exposure levels have been established for lactic acid. An air purifying respirator with acid cartridge and a HEPA filter may suffice. However, better protection is provided by a supplied-air respirator with full facepiece operated in pressure demand or other positive pressure mode. | | | | |
| Ventilation Local exhaust or general mechanical systems recommended. | | | | |
| Protective Gloves Polyethylene or Teflon | | Eye Protection Chemical/Dust Goggles or Face Mask | | Other Protective Clothing Protective Apron |
| Work/Hygiene Practices Always wash hands thoroughly after using chemical; never bring food, drink, or smoking materials into vicinity of chemicals. | | | | |

LACTIC ACID

CAS: 50-21-5

**IDENTIFICATION AND TYPICAL USES**

Lactic acid appears as a colorless or slightly yellow crystalline solid or a thick, syrupy, hygroscopic liquid with a slightly acrid odor. It is used in cultured dairy products, as a mordant in dyeing baths, adhesives, plastics, and textiles, as an acidulant, as a general purpose food additive, a solvent for cellulose formate, as a flux for soft solder, in the manufacture of cheese and confectionery, in dehairing, plumbing, and decalcifying hides, in the manufacture of lactates for food products, medicine, and as a solvent, a plasticizer, and as a catalyst in casting of phenolaldehyde resins.

RISK ASSESSMENT: HEALTH**General Assessment**

Exposure to lactic acid is possible through *inhalation* of its dusts or mists and by *ingestion*. The data in the references are limited regarding its specific toxicity. However, there are no reports of animal or human carcinogenicity or teratogenicity. Mutation data have been reported.

Inhalation of lactic acid dusts or mists will cause irritation of the eyes, nose, throat, and mucous membranes of the upper respiratory tract. Bronchial tube irritation and coughing may also occur. Lactic acid can cause dental erosion.

Skin and eye contact with concentrated solutions can result in mild to moderate irritation. On the skin, lactic acid can cause burns, irritation, and possible eczema. If allowed to remain in contact with the eye for prolonged periods, corneal edema, burns, and conjunctivitis may occur.

Ingestion of diluted solutions can cause burns to the mouth, throat, esophagus, and stomach with ab-

dominal cramps, nausea, vomiting, sweating, dyspnea, cyanosis, and vascular collapse.

☠ Acute Health Effects

The following acute (short-term) health effects may occur immediately or shortly after exposure to lactic acid:

Skin: Irritation/rash or burning feeling on contact. With possible development of eczema.

Eye: Severe irritation; may cause burns, conjunctivitis, and corneal damage.

Lung: Irritation of the nose, throat, and mucosa of the lungs and respiratory tract.

Other: Ingestion causes burns to the digestive tract with vomiting, nausea, cramps, shortness of breath, cyanosis, and vascular effects. Dental erosion is also a possibility.

☘ Chronic Health Effects

The following chronic (long-term) health effects may occur at some time after exposure to lactic acid and can last for months or even years:

Cancer Hazards: According to information presented in the references, lactic acid has not been adequately tested for its ability to cause cancer in animals. Mutation data have been reported and some scientists believe that long-term exposure to mutagens may pose a cancer risk. There is no indication that exposure to lactic acid will have this effect. Additional research is required.

Reproductive Hazard: According to information presented in the references, lactic acid has not been adequately tested for its ability to adversely affect reproduction in laboratory animals.

🕒 **Recommended Risk-Reduction Measures**

Personnel should avoid direct contact with lactic acid. The exact nature of its toxicity is not clearly understood in the references. If a less toxic chemical cannot be substituted for a hazardous substance, then *engineering controls* are the most effective method of reducing exposures.

The best protection is to enclose operations and/or provide local exhaust ventilation at the site of chemical release. While not always operationally feasible, isolating operations can also reduce exposure. Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around lactic acid. No exposure levels have been established for lactic acid. This does not mean that exposure is without health risk. Prudent risk management may require a conservative approach to respiratory protection until further data are known about lactic acid. For transient exposures, an air-purifying respirator equipped with an acid cartridge, a HEPA filter, and a dust/mist pre-filter may suffice. Greater protection is obtained using a supplied-air respirator or a self-contained breathing apparatus (SCBA) with full facepiece operated in pressure demand or other positive pressure mode. If a full facepiece is not available, then chemical goggles should be worn to protect the eyes. Whenever a chemical splash/dust hazard exists, a face shield and a rubber apron should be worn. To prevent hand and skin exposures, acid resistant gloves should be worn. Glove manufacturers should be contacted and permeation studies obtained *before* final glove selections have been made.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with lactic acid.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where lactic acid is used or stored. Other methods to reduce exposure include:

- ☑ Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not used, respiratory protection should be mandatory.
- ☑ Always ensure that proper protective clothing is worn when using chemical substances.
- ☑ Wash thoroughly immediately after exposure to lactic acid and at the end of the work shift or before eating, drinking, or smoking.
- ☑ Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of lactic acid should be communicated to all exposed or potentially exposed workers.

RISK ASSESSMENT: ENVIRONMENT

General Assessment

The environment is at risk of exposure during transportation, storage, disposal, or destruction of lactic acid. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance. Accidental spills, large or small, can result in fire, explosion, and possible contamination of the surrounding environmental mediums (water, soil, and air).

Lactic acid is considered a non-combustible solid. It may be corrosive, especially when mixed in solution. It is incompatible with nitric and hydrofluoric acid and contact can cause violent reaction. It will also corrode many common metals, including aluminum, cast iron, steel (stainless steel appears to resist corrosion). These characteristics require special consideration during any emergency situation involving a leak or spill of lactic acid.

Lactic acid can enter the environment mainly in industrial discharges or spills.

☠ **Acute Ecological Effects**

Acute (short-term) toxic effects may include the death of animals, birds, or fish and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to lactic acid.

Lactic acid has moderate acute toxicity to aquatic life. Insufficient data are available to evaluate or predict the short-term effects of lactic acid exposure to birds, plants, or land animals.

🌱 **Chronic Ecological Effects**

Chronic (long-term) toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals. Insufficient data are available to evaluate or predict the long-term effects

of lactic acid exposure to aquatic life, birds, plants, or land animals.

◆ **Water Solubility**

Lactic acid is soluble in water. Concentrations of up to 1000 milligrams and more will mix with a liter of water.

⌚ **Persistence in the Environment**

Lactic acid is slightly persistent in the aquatic environment, with a half-life of between 2 to 20 days. The half-life of a pollutant is the amount of time it takes for one half of the chemical to be degraded.

🐟 **Bioaccumulation in Aquatic Organisms**

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans.

Lactic acid can be expected to biodegrade quickly and should not accumulate in the edible tissues of fish.

🔧 **Recommended Risk-Reduction Measures**

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in a leak or spill to the environment. The correct use of DOT labeling on all containers, trucks, and rail cars will enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of lactic acid should be segregated from incompatible chemicals to minimize the risk of cross-contamination or contact. Buildings designated for storage should be equipped with appropriate fire protection systems (alarms, sprinklers, emergency lighting, portable extinguishers).

If a spill or leak to the environment has occurred, fire department, emergency response and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those trained in proper spill containment procedures. Contaminated soils should be removed for incineration and replaced with clean soil. If lactic acid should contact the water table, aquifer, or navigable waterway, time is of the essence. It is miscible in water and, therefore, total containment and remediation may not be possible. When such spills occur, the local and/or state emergency response authorities must be notified. A comprehensive emergency response or

disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of lactic acid. If lactic acid is spilled or leaked, the following specific steps are recommended:

- ☑ Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened for normal work.
- ☑ Remove ignition sources and ventilate area.
- ☑ Collect all powdered materials in safest and most convenient manner possible and deposit in sealed drums for disposal. Do NOT dry sweep (generates airborne dusts). Use a vacuum equipped with a high efficiency particulate air (HEPA) filter instead. Damp mop residue and collect for disposal. Absorb any solution spills in vermiculite, dry sand, earth, or similar material and deposit in sealed containers.
- ☑ It may be necessary to dispose of lactic acid as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving lactic acid can present a significant threat to business operations. The loss or damage of equipment or facilities can significantly affect fiscal viability. Lawsuits that may result from personnel injury/death, public exposures, and/or environmental contamination will also require a serious expenditure of resources. Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business.

🔧 **Recommended Risk-Reduction Measures**

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures dealing with safety or emergency response. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

| Emergency and First-aid Procedures Eye contact: Flush immediately with water for 15 minutes (minimum); seek medical attention. Skin contact: Remove all contaminated clothing. Immediately wash area with large amounts of soap and water. Seek medical assistance. For inhalation: Remove the person from exposure. Provide respiratory assistance and CPR. Transfer to medical facility. Lactonitrile can cause fatal cyanide poisoning. If swallowed: Contact poison control center. Unless advised otherwise, give 1 to 2 glasses of water to dilute. Do NOT induce vomiting. Use Lilly cyanide antidote kit. Seek medical attention immediately. | | | | |
| SECTION VII - PRECAUTIONS FOR SAFE HANDLING AND USE | | | | |
| Steps to be Taken in Case Material is Released or Spilled Contain spills using absorbent material (vermiculite, or other). Ventilate area of spill. Have water source available in case of fire. Store materials in DOT-approved containers. Restrict those not involved in cleanup from entering area. Notify appropriate authorities, as required by SARA III, if applicable. | | | | |
| Preferred Waste Disposal Method No citation. | | | | |
| Precautions to be Taken in Handling and Storage Lactonitrile is highly volatile. Store to avoid contact with strong oxidizers. Store in tightly closed containers in cool, well-ventilated area away from heat. Use non-sparking tools. | | | | |
| Other Precautions and Warnings Prior to working with lactonitrile, personnel should be trained on its proper handling and storage. | | | | |
| SECTION VIII - CONTROL MEASURES AND PERSONAL PROTECTIVE EQUIPMENT | | | | |
| Respiratory Protection (<i>specify type</i>) For low exposures, NIOSH-approved full facepiece respirator with organic vapor cartridge. For higher exposures, use a supplied-air respirator in continuous flow mode or a self-contained breathing apparatus (SCBA) with full facepiece and pressure demand or other positive pressure mode. | | | | |
| Ventilation Local exhaust or general mechanical systems recommended. | | | | |
| Protective Gloves Impervious Material | | Eye Protection Chemical Goggles or Face Mask | | Other Protective Clothing Protective Apron |
| Work/Hygiene Practices Always wash hands thoroughly after using chemical; never bring food, drink, or smoking materials into vicinity of chemicals. | | | | |

LACTONITRILEC₂H₄(OH)CN

CAS: 78-97-7

**IDENTIFICATION AND TYPICAL USES**

Lactonitrile is a colorless to straw-colored liquid. It is used as a solvent and as an intermediate in the production of ethyl lactate and lactic acid.

RISK ASSESSMENT: HEALTH**General Assessment**

Lactonitrile is toxic by all common routes of exposure (*ingestion, inhalation, and dermal absorption*). The toxic effects of lactonitrile are attributed to the metabolic release of cyanide, which in turn acts by inhibiting cytochrome oxidase and thus impairs cellular respiration. There are no reports to indicate that exposure causes carcinogenic, mutagenic, or teratogenic effects.

Human exposure to lactonitrile can produce severe adverse effects. The target organs are the central nervous system (CNS), lungs, cardiovascular system (CVS), skin, and eyes. In humans, exposure to lactonitrile vapors can cause respiratory stimulation, dyspnea, ataxia, convulsion, decreased body temperature, and spastic paralysis. There can be nausea, vomiting, and tightness of the chest. It is excreted in the urine as a cyanate. The blood cyanide concentration does not always show any significant increase in cyanide at low exposure concentrations. Large doses can be fatal. Skin contact results in absorption and systemic effects. Severe eye irritation is likely.

☠ Acute Health Effects

The following acute (short-term) health effects may occur immediately or shortly after exposure to lactonitrile. (Note: Exposure by any route can cause fatal cyanide poisoning. Symptoms of flushed face, chest tightness, nausea, vomiting, weakness, and shortness

of breath may lead to death. These reactions may begin hours after an overexposure.)

Skin: Irritation/rash on contact (contact dermatitis) and absorption.

Eye: Severe irritation, conjunctivitis, and damage.

Lung: Irritation of the nose, throat, and lungs following exposure.

CNS: Inhalation of high concentrations of the vapor may cause sleepiness, dizziness, loss of consciousness, or death.

☼ Chronic Health Effects

The following chronic (long-term) health effects may occur at some time after exposure to lactonitrile and can last for months or even years:

Cancer Hazards: According to the references, lactonitrile has not been tested for its ability to cause cancer in animals.

Reproductive Hazard: According to the references, lactonitrile has not been significantly tested for its ability to adversely affect reproduction.

Other Chronic Effects: High exposures may damage the nervous system, liver, and kidneys. Very irritating substances may affect the lungs. It is not known whether lactonitrile causes permanent lung damage. Prolonged or repeated skin contact may cause itching, rash, and possible dermatitis.

🛡 Recommended Risk-Reduction Measures

Personnel should avoid direct contact with lactonitrile. Unless a less toxic chemical can be substituted for a hazardous substance, *engineering controls* are the most effective method of reducing exposures. The best protection is to enclose operations and/or provide local exhaust ventilation at the site of chemical release. While not always operationally feasible, isolating operations can also reduce exposure. Using

respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around lactonitrile. No exposure levels have been established for lactonitrile. However, this does not mean that exposure is without risk. For the best protection, a supplied-air respirator operated in continuous flow mode or a self-contained breathing apparatus (SCBA) with full facepiece operated in pressure demand are the recommended respiratory protection methods of choice. If a full facepiece is not available, then chemical goggles should be worn to protect the eyes. Whenever a chemical splash hazard exists, a face shield and a protective apron should be worn. To prevent hand and skin exposures, impervious gloves should be used. Glove manufacturers should be contacted and permeation studies obtained *before* final glove selections have been made.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with lactonitrile.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where lactonitrile is used or stored.

Medical testing of personnel with frequent or potentially high exposure, should be provided before beginning work and at regular intervals thereafter (e.g., annually). These tests should include:

- Lung function (pulmonary function) test.

If symptoms develop or overexposure is suspected, the following tests may be useful:

- Blood cyanide test and/or urine thiocyanate test (currently, a blood cyanide level over 0.1 mg/l or urine thiocyanate over 20 mg/l indicates overexposure).
- Maintain close medical surveillance. Slow release of cyanide from absorbed lactonitrile may cause delayed symptoms.
- Liver and kidney function tests.

Other methods to reduce exposure include:

- Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not used, respiratory protection should be mandatory.
- Always ensure that proper protective clothing is worn when using chemical substances.

- Wash thoroughly immediately after exposure to lactonitrile and at the end of the work shift or before eating, drinking, or smoking.
- Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of lactonitrile should be communicated to all exposed workers.

RISK ASSESSMENT: ENVIRONMENT

General Assessment

The environment is at risk of exposure during transportation, storage, disposal, or destruction of lactonitrile. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance. Accidental spills, large or small, can result in fire, explosion, and possible contamination of the surrounding environmental mediums (water, soil, and air).

Lactonitrile is considered a highly flammable liquid and a poison. Because of its low flash point and high boiling point, it is classified as a Class IIIA combustible liquid (per OSHA 29 CFR 1910.106). Lactonitrile vapors can form explosive mixtures in air. It reacts with strong oxidizers and acids, liberating heat along with pressure increase. It will also react with alkalis to evolve hydrogen cyanide. Thus, contact with these incompatible materials, especially under closed conditions, can cause dangerous reactions. These characteristics require special consideration during any emergency situation involving a leak or spill of lactonitrile. Should lactonitrile come into contact with incompatible materials either during use, transportation, or storage, the formation of highly toxic and/or highly explosive commodities is extremely possible.

The proper disposal/destruction method for lactonitrile is to mix it with a combustible solvent and burn the mixture in a chemical incinerator equipped with an afterburner and air scrubber.

Lactonitrile can enter the environment through manufacturing effluents, municipal waste treatment discharges, and spills.

☠ Acute Ecological Effects

Acute (short-term) toxic effects may include the death of animals, birds, or fish and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to lactonitrile. This chemi-

cal has slight acute toxicity to aquatic life. No data are available on the short-term effects of lactonitrile to plants or land animals.

☪ *Chronic Ecological Effects*

Chronic toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals. Lactonitrile has slight chronic toxicity in aquatic life. No data are available on the long-term effects of lactonitrile to plants, birds, or land animals.

💧 *Water Solubility*

Lactonitrile is highly soluble in water. Concentrations of 1000 milligrams and more will mix with a liter of water.

⌚ *Persistence in the Environment*

Lactonitrile is slightly persistent in water, with a half-life of between 2 to 20 days. The half-life of a pollutant is the amount of time it takes for one half of the chemical to be degraded. In alkaline waters, it is expected to degrade to form hydrogen cyanide.

🐟 *Bioaccumulation in Aquatic Organisms*

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans.

The concentration of lactonitrile found in fish tissues is expected to be about the same as the average concentration of lactonitrile in water from which the fish was taken.

🛡️ *Recommended Risk-Reduction Measures*

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in a leak or spill to the environment. The correct use of DOT labeling (per the MSDS) on all containers, trucks, and rail cars will enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of lactonitrile should be segregated from incompatible chemicals to minimize the risk of cross-contamination or contact. Buildings designated for storage should be equipped with appropriate fire pro-

tection systems (alarms, sprinklers, emergency lighting, portable extinguishers).

If a spill or leak to the environment has occurred, fire department, emergency response, and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those trained in proper spill containment procedures using non-sparking tools. Contaminated soils should be removed for incineration and replaced with clean soil. If lactonitrile should contact the water table, aquifer, or navigable waterway, time is of the essence. It is readily miscible in water and, therefore, total containment and remediation may not be possible. When such spills occur, the local and/or state emergency response authorities must be notified. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of lactonitrile. If lactonitrile is spilled or leaked, the following specific steps are recommended:

- ☑ Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened to normal work.
- ☑ Remove all ignition sources.
- ☑ Ventilate area of spill or leak.
- ☑ Absorb liquids in vermiculite, dry sand, earth, or a similar material and deposit in sealed containers.
- ☑ Keep lactonitrile out of a confined space, such as a sewer, because of the possibility of explosion (unless the sewer is designed to prevent the buildup of explosive concentrations).
- ☑ It may be necessary to dispose of lactonitrile as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving lactonitrile can present a significant threat to business operations. The loss or damage of equipment or facilities can significantly affect fiscal viability. Lawsuits that may result from personnel injury/death, public exposures, and/or environmental contamination will also require a serious expenditure of resources. Media attention surrounding an injury, death, or environmental damage

can also result in a loss of profits and loss of current as well as future business.

🕒 Recommended Risk-Reduction Measures

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures dealing with safety or emergency response. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

LAURYL ALCOHOL

CAS: 112-53-8

**IDENTIFICATION AND TYPICAL USES**

Lauryl alcohol is a colorless liquid with a floral odor and fatty, waxy taste. It can also be a colorless solid below 75°F (24°C). It is used in synthetic detergents, in lubrication additives, in pharmaceuticals, in rubber and textiles, in the manufacture of perfumes, and as a flavoring agent.

RISK ASSESSMENT: HEALTH***General Assessment***

The toxicity of lauryl alcohol is much lower in comparison to most other alcohols. Lauryl alcohol is primarily toxic to humans by *inhalation* of its heated vapors. *Ingestion* can also produce mild toxicity. Skin contact can cause topical damage but dermal absorption is not likely. There are conflicting reports in the references to indicate that lauryl alcohol may cause carcinogenic effects in test animals.

Inhalation can cause irritation of the eyes, nose, throat, upper respiratory tract, and associated mucosa. Vapor exposure can also increase the toxic effects of other chemicals being inhaled.

Liquid contact with the eyes causes immediate burning and stinging with lachrymation and reflex closure of the lids. There may be injury to the corneal epithelium and possible hyperemia (excessive blood) of the conjunctiva. Skin contact results in drying and cracking which can lead to secondary infections and dermatitis.

Acute Health Effects

The following acute (short-term) health effects may occur immediately or shortly after exposure to lauryl alcohol:

Skin: Causes dryness and cracking leading to dermatitis and possible infection.

Eye: Severe irritation with burning and stinging with possible damage to the cornea and conjunctiva.

Lung: Irritation of the eyes, nose, throat, and respiratory tract.

Chronic Health Effects

The following chronic (long-term) health effects may occur at some time after exposure to lauryl alcohol and can last for months or even years:

Cancer Hazards: Lauryl alcohol has been shown to cause cancer in limited test studies on laboratory animals. However, data are conflicting and inconclusive and no determinations have been made on its carcinogenic potential in humans.

Reproduction: According to the references, lauryl alcohol has not been adequately tested for its ability to adversely affect reproduction in test animals.

Other Chronic Effects: Prolonged skin contact can cause dermatitis.

Recommended Risk-Reduction Measures

Even though lauryl alcohol is considered to be of relatively low toxicity, personnel should still avoid direct contact. The exact nature of its long-term effects on humans is not clearly understood on the references. The data are conflicting and inconclusive in this regard.

The best risk reduction measure is to use a less toxic chemical as a substitute for a lauryl alcohol. However, based upon the fact that the toxicity of lauryl alcohol is considered to be much lower compared to other alcohols, substitution may not be an alternative. Therefore, *engineering controls* are the most effective methods of reducing exposures. The best protection is to enclose operations and/or provide local exhaust ventilation at the site of chemical release.

While not always operationally feasible, isolating operations can also reduce exposure risk.

Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around lauryl alcohol. No exposure levels have been established for lauryl alcohol. However, this does not mean that exposure is without risk. For low or infrequent exposures, an air-purifying respirator with an organic vapor cartridge will suffice. For higher exposures, a supplied-air respirator with full facepiece operated in positive pressure mode, or a self-contained breathing apparatus (SCBA) with full facepiece and operated in pressure demand mode are the recommended respiratory protection methods of choice. If a full facepiece is not available, then chemical goggles should be worn to protect the eyes. Whenever a chemical splash hazard exists, a face shield and a protective apron should be worn. To prevent hand and skin exposures, impervious butyl rubber gloves should be used. Glove manufacturers should be contacted and permeation studies obtained *before* final glove selections have been made.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with lauryl alcohol.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where lauryl alcohol is used or stored.

If symptoms develop or overexposure is suspected, the following medical tests are recommended:

- ☑ Skin testing with dilute lauryl alcohol to help diagnose allergy (performed by a qualified allergist).

Any medical evaluation should include a careful history of past and present symptoms with an examination. Medical tests that look for existing damage are not a substitute for controlling exposures.

Other methods to reduce exposure include:

- ☑ Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not used, respiratory protection should be mandatory.
- ☑ Always ensure that proper protective clothing is worn when using chemical substances.

- ☑ Wash thoroughly immediately after exposure to lauryl alcohol and at the end of the work shift or before eating, drinking, or smoking.
- ☑ Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of lauryl alcohol should be communicated to all exposed workers.

RISK ASSESSMENT: ENVIRONMENT

General Assessment

The environment is at risk of exposure during transportation, storage, disposal, or destruction of lauryl alcohol. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance. Accidental spills, large or small, can result in fire, explosion, and possible contamination of the surrounding environmental mediums (water, soil, and air).

Lauryl alcohol is considered a combustible liquid (according to OSHA 29 CFR 1910.106). Its high flash point and boiling point present a mild fire and explosion hazard concern. Also, because it is incompatible with a number of common materials, especially strong oxidizers, contact can result in violent and explosive reactions. It can also form explosive mixtures with air in enclosed or confined areas and may ignite on contact with heat, fire, or sparks. These characteristics require special consideration during any emergency situation involving a leak or spill of lauryl alcohol.

Lauryl alcohol can enter the environment through unchecked industrial discharges into effluents and through spills.

☠ *Acute Ecological Effects*

Acute (short-term) toxic effects may include the death of animals, birds, or fish, and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to lauryl alcohol. Lauryl alcohol has slight acute toxicity to aquatic life. Insufficient data are available to evaluate the short-term effects of lauryl alcohol plants, birds, or land animals.

☪ *Chronic Ecological Effects*

Chronic toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals. Insufficient data are available to evaluate

or predict the long-term effects of lauryl alcohol to aquatic life, plants, birds, or land animals.

💧 **Water Solubility**

Lauryl alcohol is highly soluble in water. Concentrations of 1000 milligrams and more can be expected to mix with a liter of water.

⌚ **Persistence in the Environment**

Lauryl alcohol is slightly persistent in water, with a half-life of between 2 to 20 days. The half-life of a pollutant is the amount of time it takes for one-half of the chemical to be degraded. About 90% of lauryl alcohol will eventually end up in the air; the remainder will end up in water.

🐟 **Bioaccumulation in Aquatic Organisms**

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans.

The concentration of lauryl alcohol found in fish tissues is expected to be about the same as the average concentration of lauryl alcohol in water from which the fish was taken.

🛡️ **Recommended Risk-Reduction Measures**

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in a leak or spill to the environment. The correct use of labeling on all containers, trucks, and rail cars will enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of lauryl alcohol should be segregated from incompatible chemicals to minimize the risk of cross-contamination or contact. Buildings designated for storage should be equipped with appropriate fire protection systems (alarms, sprinklers, emergency lighting, portable extinguishers).

If a spill or leak to the environment has occurred, fire department, emergency response, and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those trained in proper spill containment procedures. Contaminated soils should be removed for incineration and replaced with clean soil. If lauryl alcohol should contact the water table, aquifer, or navigable waterway, time is of the essence. It is highly soluble in

water and, therefore, containment and remediation may not be entirely possible. When such spills occur, the local and/or state emergency response authorities must be notified. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of lauryl alcohol. If lauryl alcohol is spilled or leaked, the following specific steps are recommended:

- ☑ Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened for normal work.
- ☑ Ventilate area of spill or leak.
- ☑ Remove all ignition sources.
- ☑ Absorb liquids in vermiculite, dry sand, earth, or a similar material and deposit in sealed containers. Use non-sparking tools.
- ☑ It may be necessary to dispose of lauryl alcohol as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving lauryl alcohol can present a moderate threat to business operations. The loss or damage of equipment or facilities can significantly affect fiscal viability. Lawsuits that may result from personnel injury/death, public exposures, and/or environmental contamination will also require a serious expenditure of resources. Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business. Always remember that anytime the terms "cancer" or "carcinogen" are used, public emotion, hysteria, and ignorance can run equally high. This should be carefully considered whenever developing or implementing public relations policies.

🛡️ **Recommended Risk-Reduction Measures**

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures or policies intended to manage the use of chemicals in the workplace. A company official should be pre-designated as a public relations officer with specific training in

dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

| SECTION VI - HEALTH HAZARD DATA | | | | |
| Primary Route(s) of Entry: | | Inhalation? X | Absorption (skin)? | Ingestion? X |
| Health Hazards INHALATION: Acute encephalopathy with seizures, coma, and death. There may be ataxia, headache, repeated vomiting, stupor, hallucinations, tremors, convulsions, and coma. Chronic exposures lead to central nervous system and cardiovascular system effects and may cause kidney damage. Inhaling dusts can cause gastritis and liver changes. There can be loss of appetite, malaise, insomnia, facial pallor, irritability, and anemia. SKIN & EYES: Skin and eye contact with powdered fibers can result in scratches and minor irritation. INGESTION: Ingested lead is poorly absorbed. If it does enter the bloodstream, it can have many of effects noted for inhalation. It is a systemic poison that accumulates in body organs. | | | | |
| Carcinogenicity Probable Human Questioned Animal | NTP Listed? No | IARC Cancer Review Group? Group 2B | OSHA Regulated? 29 CFR 1910.1025 | Target Organs? Eyes, GI tract, blood, CNS, CVS, gingival tissues. |
| Medical Conditions Generally Aggravated by Exposure Nervous system disorders (epilepsy), kidney diseases, hypertension, infertility, and anemia. | | | | |
| Emergency and First-aid Procedures <u>Eye contact:</u> Flush immediately with water for 15 minutes (minimum); seek medical attention. <u>Skin contact:</u> Remove all contaminated clothing. Wash contaminated skin with soap and water. For <u>inhalation:</u> Remove the person from exposure. Provide respiratory assistance and CPR. Transfer to medical facility. <u>If swallowed:</u> Never attempt to give anything by mouth to an unconscious or convulsing person. If large quantities are ingested, induce vomiting with Syrup of Ipecac and call physician. | | | | |
| SECTION VII - PRECAUTIONS FOR SAFE HANDLING AND USE | | | | |
| Steps to be Taken in Case Material is Released or Spilled Remove all sources of ignition. Restrict those not involved in cleanup from entering area. Collect powdered material in the most convenient way possible and deposit in sealed containers. Do NOT dry sweep (creates airborne dust). Use HEPA vacuum instead. Damp mop and collect residue. | | | | |
| Preferred Waste Disposal Method Lead is a naturally occurring metal and does not pose a significant threat to the environment. | | | | |
| Precautions to be Taken in Handling and Storage Containers should be protected against physical damage. Store in tightly closed containers in a cool, dry, well-ventilated area away from acids, caustics, heat, flame, and direct sunlight. Keep lead dry. | | | | |
| Other Precautions and Warnings Whenever bulk or finely powdered lead is used, handled, manufactured, or stored, use explosion-proof electrical equipment and fittings. | | | | |
| SECTION VIII - CONTROL MEASURES AND PERSONAL PROTECTIVE EQUIPMENT | | | | |
| Respiratory Protection (<i>specify type</i>) Exposure level is low and difficult to monitor. Use a respirator with particulate (dust/fume/mist) filter. Otherwise use a supplied-air respirator or self-contained breathing apparatus in continuous flow mode. | | | | |
| Ventilation Local exhaust or general mechanical systems recommended. | | | | |
| Protective Gloves Suitable to protect from skin contact | Eye Protection Chemical/Dust Goggles | | Other Protective Clothing N/A | |
| Work/Hygiene Practices Always wash hands thoroughly after working with lead powders and dusts; never bring food, drink, or smoking materials into vicinity of lead powders. | | | | |

LEAD

Pb

CAS: 7439-92-1

**IDENTIFICATION AND TYPICAL USES**

Lead is a bluish-white or gray, heavy, soft, ductile metallic solid. It is metallic element of atomic number 82, group IVA of the periodic table, atomic weight 207.2, valance of 2,4, and four stable isotopes. It is used in storage batteries, tertaethyllead (a former gaso-line additive), in chemical reaction equipment (piping, tank linings), in solder, in fusible alloys, in type metal, for vibration damping in heavy construction, in foil, as a protective barrier against certain radioactive isotopes as well as against non-ionizing radiation (X-rays), and in petroleum refining.

RISK ASSESSMENT: HEALTH***General Assessment***

Lead is a systemic human poison through *inhalation* of finely divided powder and, to a lesser degree, *in-gestion* either of foods or liquids containing lead or direct ingestion of lead itself (not a typical occupational exposure). Skin contact with lead dusts may result in scratching, itching, and possible scarring. The same holds true for eye contact. Ingested lead is poorly absorbed, with most of it being eliminated in the feces. The majority of the lead that is absorbed is collected in the liver and excreted in the bile. Therefore, large doses over a long period are required to significantly affect human health through ingestion. The IARC lists lead as a probable human carcinogen with insufficient evidence (Group 2B). Human mutation data have been reported and it is an experimental teratogen.

Inhalation causes acute encephalopathy with ataxia, repeated vomiting, headaches, stupor, hallucinations, tremors, convulsions or seizures, coma, and death. Other central nervous system effects include weight loss, malnutrition, restlessness, irritability, tingling in the wrists and ankles, and possible permanent brain damage. There can be kidney degradation with glomular atrophy, interstitial fibrosis, and sclerosis of vessels. There can be gastritis, changes in the liver,

and accumulation in the bones and teeth. Heavy intoxication can often be detected by the formation of a dark line on the gum margins (the "lead line"). Lead causes the red blood cells to become brittle and more fragile. This increased fragility allows them to be destroyed more rapidly than normal, causing anemia. Lead has an experimental half-life in the human body of 1460 days.

☠ *Acute Health Effects*

The following acute (short-term) health effects may occur immediately or shortly after exposure to lead:

Skin: Irritation/scratching on contact with particles.

Eye: Irritation/scratching on contact with particles.

Lung: Possible irritation of the nose, throat, and lungs following exposure to fibers and dusts.

CNS: A variety of effects including stupor, hallucinations, delirium, parasthesia, headaches, convulsions and seizures, coma, and death.

● *Chronic Health Effects*

The following chronic (long-term) health effects may occur at some time after exposure to lead and can last for months or even years:

Cancer Hazards: According to information presented in the references, lead has been tested for its ability to cause cancer in test animals and the results are conflicting and inconclusive. IARC lists it as a probable human carcinogen with insufficient evidence (Group 2B). Human mutation data have been reported and many scientists believe that exposure to mutagenic compounds may pose a cancer risk in the long-term.

Reproductive Hazard: According to information presented in the references, lead has been shown to adversely affect reproduction in test animals. There may be a decreased sex drive, impotence, sterility in males, decreased fertility and abnormal menstrual cycles in females and possible spontaneous fetal abortions in

females. Unborn children may suffer neurological damage or developmental problems due to excessive lead exposures by pregnant women.

Other Chronic Effects: Long-term exposure can lead to appetite loss, nausea, metallic taste in the mouth, a dark "lead line" on the gingival tissues in the mouth, constipation, anxiety, anemia, facial pallor, tiredness, weakness, insomnia, chronic headache, nervousness, irritability, tremors, tingling and numbness in the extremities, muscle and joint pain, colic, abdominal pain, kidney disease, and liver damage.

🕒 Recommended Risk-Reduction Measures

Personnel should avoid direct contact with lead. *Engineering controls* are always the most effective method of reducing exposures. The best protection, especially when working with fine powders and dusts of lead, is to enclose operations and/or provide explosion-proof, local exhaust ventilation at the site of powder/dust release. While not always operationally feasible, isolating operations can also reduce exposure. Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around lead. The exposure level is extremely low (0.050 mg/m^3) and difficult to accurately monitor. A respirator equipped with a dust/mist/fume filter may suffice for low or infrequent (transient) exposures. However, a supplied-air respirator operated in continuous flow mode or a self-contained breathing apparatus (SCBA) with full facepiece in pressure demand mode will provide the best respiratory protection. If a full facepiece respirator is not available, then dust goggles or safety glasses with side shields attached should be worn to protect the eyes. To prevent hand and skin exposures, suitable gloves should be used.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with lead.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where lead is used or stored.

Before beginning employment with lead, and at regular intervals thereafter (e.g., annually), the following medical tests are recommended:

- Blood lead levels and blood pressure (baseline).
- Complete blood count (establish baseline).

If symptoms develop or overexposure is suspected, the following additional tests may be useful:

- Blood lead levels and blood pressure (compare to baseline).
- Complete blood count for microcytic anemia and basophilic stippling, blood urea nitrogen (BUN) of creatinine, and zinc protoporphyrin (ZPP).
- Examination of the central and peripheral nervous systems.
- Visual examination of the gingival gum line for the appearance of a dark "lead line" on the tissues.

Other methods to reduce exposure include:

- Where possible, enclose operations and use local exhaust ventilation at the site where lead powder or dust is worked. If local exhaust ventilation or enclosure is not used, respiratory protection should be mandatory.
- Always ensure that proper protective clothing is worn when working with lead compounds.
- Wash thoroughly immediately after exposure to lead and at the end of the work shift or before eating, drinking, or smoking. Clothing contaminated with lead dusts or powders should not be taken home.
- Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of lead should be communicated to all potentially exposed workers.
- Additional exposure control measures and engineering controls are provided by OSHA in 29 CFR 1910.1025 (Lead).

RISK ASSESSMENT: ENVIRONMENT

General Assessment

Lead occurs naturally in the environment. However, the environment is still at risk of exposure during transportation, storage, disposal, or destruction of lead. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of lead materials, especially the dusts and powders. Accidental contact with a variety of incompatible materials can result in fire, explosion, and possible contamination of the surrounding environmental mediums (water, soil, and, to a lesser degree, air).

Lead is considered a non-combustible solid in bulk form. If its dusts and powders become airborne in sufficient quantities or in enclosed areas, there may

be an explosion hazard. It is incompatible with oxidizing agents and contact can cause fire or explosion. These characteristics require special consideration during any emergency situation involving a leak or spill of lead. Should lead ever come into contact with incompatible substances such as oxidizers, acids, or hydrogen peroxide, during transportation or storage, the formation of highly explosive commodities is extremely possible.

Lead is one of the most abundant metals in the earth's crust. It is used extensively across a broad spectrum of industries for a large variety of purposes. Because of its frequent use and common occurrence, lead enters the environment from point and non-point sources.

☠ *Acute Ecological Effects*

Acute (short-term) toxic effects may include the death of animals, birds, or fish and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to lead.

This metal has high acute toxicity to aquatic life and high toxicity to birds. Insufficient data are available on the short-term effects of lead exposure to plants or land animals.

🕒 *Chronic Ecological Effects*

Chronic (long-term) toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals.

Lead has high chronic toxicity in aquatic life. Lead causes nerve and behavioral effects in humans and could cause similar long-term effects in birds and land animals. Insufficient data are available on the long-term effects of lead to plants.

💧 *Water Solubility*

Lead and its compounds range in their respective water solubilities from highly soluble to practically insoluble.

🕒 *Persistence in the Environment*

Lead and its compounds are highly persistent in water, with a half-life greater than 200 days. The half-life of a pollutant is the amount of time it takes for one half of the chemical to be degraded.

🐟 *Bioaccumulation in Aquatic Organisms*

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans.

The concentration of lead found in the edible tissues of fish is expected to be much higher than the average concentration of lead found in the water from which the fish was taken.

🛑 *Recommended Risk-Reduction Measures*

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in the contamination of the environment. The correct use of DOT labeling (per the MSDS) on all containers, trucks, and rail cars will enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of lead should be segregated from incompatible chemicals to minimize the risk of cross-contamination or contact. Buildings designated for storage should be equipped with appropriate fire protection systems (alarms, sprinklers, emergency lighting, portable extinguishers).

If a spill or leak to the environment has occurred, fire department, emergency response and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those trained in proper spill containment procedures. Contaminated soils should be removed and replaced with clean soil. When environmental contamination occurs, the local and/or state emergency response authorities may require notification. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of lead. If lead is spilled or leaked, the following specific steps are recommended:

- ☑ Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened for normal work.
- ☑ Remove all ignition sources.
- ☑ Collect powdered materials in the safest manner possible and deposit in sealed containers. Do NOT dry sweep (generates airborne dust). Use a vacuum equipped with a high-efficiency particulate air (HEPA) filter. Damp mop residues.
- ☑ It may be necessary to dispose of lead as a hazardous waste. The responsible state agency or the regional office of the federal Environmental

Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving lead can present a significant threat to business operations. The loss or damage of equipment or facilities due to explosion or fire can significantly affect fiscal viability. Lawsuits that may result from personnel injury/death, public exposures, and/or environmental contamination will also require a serious expenditure of resources. Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business. Always remember that anytime the terms "cancer," "carcinogen," or "reproductive hazard" are used, public emotion, hysteria, and ignorance can run equally high. This is also true whenever the words "lead" and "exposure" are used together. This must be carefully considered whenever developing or implementing a public relations policy.

Recommended Risk-Reduction Measures

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures for dealing with safety or emergency response. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

| Primary Route(s) of Entry: | | Inhalation? X | Absorption (skin)? X | Ingestion? |
| Health Hazards INHALATION: Symptoms include headache, insomnia, persistent vomiting, blurred vision and other visual disturbances, irritability, facial pallor, pale lips, anemia, hypertension, anxiety, restlessness, delirium, hallucinations, convulsions, seizures, coma, and the appearance of a dark line along the gums in the mouth ("lead line"). ABSORPTION: Skin and eye contact can cause irritation. Dermal absorption can occur. INGESTION: Unlikely. If it occurs, can cause metallic taste, dry throat, abdominal pain, nausea and vomiting, diarrhea, constipation, peripheral circulatory system collapse, muscle weakness, headache, insomnia, kidney damage, coma, and death. | | | | |
| Carcinogenicity Probable Human Questioned Animal | NTP Listed? NTP-2 | IARC Cancer Review Group? Group 2B | OSHA Regulated? 29 CFR 1910.1025 (Lead) | Target Organs? GI tract, blood, CNS, kidneys, gingival tissues. |
| Medical Conditions Generally Aggravated by Exposure Nervous system disorders (epilepsy), kidney diseases, hypertension, infertility, and anemia. | | | | |
| Emergency and First-aid Procedures Eye contact: Flush immediately with water for 15 minutes (minimum); seek medical attention. Skin contact: Remove all contaminated clothing. Wash contaminated skin with soap and water. For inhalation: Remove the person from exposure. Provide respiratory assistance and CPR. Transfer to medical facility. If swallowed: Never attempt to give anything by mouth to an unconscious or convulsing person. If large quantities are ingested, induce vomiting with Syrup of Ipecac and call physician. | | | | |
| SECTION VII - PRECAUTIONS FOR SAFE HANDLING AND USE | | | | |
| Steps to be Taken in Case Material is Released or Spilled Remove all sources of ignition. Restrict those not involved in cleanup from entering area. Collect powdered material in the most convenient way possible and deposit in sealed containers. Do NOT dry sweep (creates airborne dust). Use HEPA vacuum instead. Damp mop and collect residue. | | | | |
| Preferred Waste Disposal Method Convert to nitrates by adding nitric acid. Evaporate to a paste in a fume hood. Add water and hydrogen sulfide. Filter, wash, and dry the precipitate (lead sulfide), package, and ship to supplier. | | | | |
| Precautions to be Taken in Handling and Storage Containers should be protected against physical damage. Store in tightly closed containers in a cool, dry, well-ventilated area away from acids, caustics, heat, flame, and direct sunlight. | | | | |
| Other Precautions and Warnings Wear appropriate personal protective equipment. | | | | |
| SECTION VIII - CONTROL MEASURES AND PERSONAL PROTECTIVE EQUIPMENT | | | | |
| Respiratory Protection (<i>specify type</i>) Exposure level is low and difficult to monitor. Use a respirator with particulate (dust/fume/mist) filter. Otherwise use a supplied-air respirator or self-contained breathing apparatus in continuous flow mode. | | | | |
| Ventilation Local exhaust or general mechanical systems recommended. | | | | |
| Protective Gloves Suitable to protect from skin contact | Eye Protection Chemical/Dust Goggles | Other Protective Clothing N/A | | |
| Work/Hygiene Practices Always wash hands thoroughly after working with lead acetate powders and dusts; never bring food, drink, or smoking materials into vicinity of lead acetate powders. | | | | |

LEAD ACETATE

CAS: 301-04-2

**IDENTIFICATION AND TYPICAL USES**

Lead acetate appears as white crystals or flakes with a slight, vinegar-like odor. The commercial grades may be brown or gray lumps. It is used in the dyeing of textiles, in waterproofing, in the making of certain varnishes, in chrome pigments, in the gold cyanidation process, in insecticides, in anti-fouling paints, as an analytical reagent, and in hair dyes.

RISK ASSESSMENT: HEALTH**General Assessment**

Lead acetate is toxic through *inhalation*, *ingestion*, and dermal *absorption*. It should be noted that ingestion poses no real toxic effect in small amounts, but repeated (chronic) ingestion can cause serious problems subsequent to lead poisoning. The IARC lists lead acetate as a probable human carcinogen with insufficient evidence (Group 2B). Mutation data have been reported. While no specific teratogenic data are documented for the acetate, lead itself is considered a teratogen with reproductive effects also being reported.

Acute poisoning is rare by any route of exposure. Inhalation of lead and possibly the acetate causes acute encephalopathy with ataxia, repeated vomiting, headaches, stupor, hallucinations, tremors, convulsions or seizures, coma, and death. Other central nervous system effects include weight loss, malnutrition, restlessness, irritability, tingling in the wrists and ankles, and possible permanent brain damage. There can be kidney degradation with glomerular atrophy, interstitial fibrosis, and sclerosis of vessels. There may also be gastritis, changes in the liver, and accumulation of lead in the bones and teeth. Heavy intoxication can often be detected by the formation of a dark line on the gum margins (the "lead line"). Lead causes the red blood cells to become brittle and more fragile. This increased fragility allows them to be destroyed more rapidly than normal causing anemia. Lead accumulates in bone on prolonged or repeated expo-

sure. It has an experimental half-life in the body of 1460 days.

☠ Acute Health Effects

The following acute (short-term) health effects may occur immediately or shortly after exposure to lead:

Skin: Irritation/scratching on contact with particles.

Eye: Irritation/scratching on contact with particles.

Lung: Possible irritation of the nose, throat, and lungs following exposure to powders and dusts.

CNS: A variety of effects including stupor, hallucinations, delirium, parasthesia, headaches, convulsions and seizures, coma, and death.

☪ Chronic Health Effects

The following chronic (long-term) health effects may occur at some time after exposure to lead and can last for months or even years:

Cancer Hazards: According to information presented in the references, lead has been tested for its ability to cause cancer in test animals and the results are conflicting and inconclusive. IARC lists it as a probable human carcinogen with insufficient evidence (Group 2B). Human mutation data have been reported and many scientists believe that exposure to mutagenic compounds may pose a cancer risk in the long-term.

Reproductive Hazard: According to information presented in the references, lead has been shown to adversely affect reproduction in test animals. There may be a decreased sex drive, impotence, sterility in males, decreased fertility and abnormal menstrual cycles in females and possible spontaneous fetal abortions in females. Unborn children may suffer neurological damage or developmental problems due to excessive lead exposures by pregnant women.

Other Chronic Effects: Long-term exposure can lead to appetite loss, nausea, metallic taste in the mouth, a dark "lead acetate line" on the gingival tissues in the

mouth, constipation, anxiety, anemia, facial pallor, tiredness, weakness, insomnia, chronic headache, nervousness, irritability, tremors, tingling and numbness in the extremities, muscle and joint pain, colic, abdominal pain, kidney disease, and liver damage.

🕒 **Recommended Risk-Reduction Measures**

Personnel should avoid direct contact with lead acetate. *Engineering controls* are always the most effective method of reducing exposures. The best protection, especially when working with fine powders and dusts of lead acetate, is to enclose operations and/or provide explosion-proof, local exhaust ventilation at the site of powder/dust release. While not always operationally feasible, isolating operations can also reduce exposure. Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around lead acetate. The exposure level (for lead) is extremely low (0.050 mg/m^3) and difficult to accurately monitor. A respirator equipped with a dust/mist/fume filter may suffice for low or infrequent (transient) exposures. However, a supplied-air respirator operated in continuous flow mode or a self-contained breathing apparatus (SCBA) with full facepiece in pressure demand mode will provide the best respiratory protection. If a full facepiece respirator is not available, then dust goggles or safety glasses with side shields attached should be worn to protect the eyes. To prevent hand and skin exposures, suitable gloves should be used.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with lead acetate.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where lead acetate is used or stored.

Before beginning employment with lead acetate, and at regular intervals thereafter (e.g., annually), the following medical tests are recommended:

- Blood lead levels and blood pressure (baseline).
- Complete blood count (establish baseline).

If symptoms develop or overexposure is suspected, the following additional tests may be useful:

- Blood lead levels and blood pressure (compare to baseline).

- Complete blood count for microcytic anemia and basophilic stippling, blood urea nitrogen (BUN) of creatinine, and zinc protoporphyrin (ZPP).
- Examination of the central and peripheral nervous systems.
- Visual examination of the gingival gum line for the appearance of a dark "lead line" on the tissues.

Other methods to reduce exposure include:

- Where possible, enclose operations and use local exhaust ventilation at the site where lead acetate powder or dust is worked. If local exhaust ventilation or enclosure is not used, respiratory protection should be mandatory.
- Always ensure that proper protective clothing is worn when working with lead compounds.
- Wash thoroughly immediately after exposure to lead acetate and at the end of the work shift or before eating, drinking, or smoking. Clothing contaminated with lead acetate dusts or powders should not be taken home.
- Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of lead acetate should be communicated to all potentially exposed workers.
- Additional exposure control measures and engineering controls are provided by OSHA in 29 CFR 1910.1025 (Lead).

RISK ASSESSMENT: ENVIRONMENT

General Assessment

Lead occurs naturally in the environment. However, the environment is still at risk of exposure during transportation, storage, disposal, or destruction of lead acetate. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of lead acetate materials, especially the dusts and powders. Accidental contact with a variety of incompatible materials can result in fire, explosion, and possible contamination of the surrounding environmental mediums (water, soil, and, to a lesser degree, air).

Lead acetate is considered a non-combustible solid in bulk form. If its dusts and powders become airborne in sufficient quantities or in enclosed areas, there may be an explosion hazard. It is incompatible with oxidizing agents, acids, hydrogen peroxide, reactive metals (sodium, potassium), resorcinol, salicylic acid, phenol, chloral hydrate, sulfites, vegetable infu-

sions, alkalis, tannin, phosphates, soluble sulfates, citrates, chlorides, carbonates, and tartrates, and contact can cause fire or explosion. These characteristics require special consideration during any emergency situation involving a leak or spill of lead acetate. Should lead acetate ever come into contact with these incompatible substances either during use, transportation, or storage, the formation of highly explosive commodities is extremely possible.

Lead is one of the most abundant metals in the earth's crust. It is used extensively across a broad spectrum of industries for a large variety of purpose. Because of its frequent use and common occurrence, lead enters the environment from point and non-point sources.

☠ *Acute Ecological Effects*

Acute (short-term) toxic effects may include the death of animals, birds, or fish and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to lead.

This metal has high acute toxicity to aquatic life and high toxicity to birds. Insufficient data are available on the short-term effects of lead exposure to plants or land animals.

🕒 *Chronic Ecological Effects*

Chronic (long-term) toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals.

Lead has high chronic toxicity in aquatic life. Lead causes nerve and behavioral effects in humans and could cause similar long-term effects in birds and land animals. Insufficient data are available on the long-term effects of lead to plants.

💧 *Water Solubility*

Lead and its compounds range in their respective water solubilities from highly soluble to practically insoluble.

🕒 *Persistence in the Environment*

Lead is highly persistent in water, with a half-life greater than 200 days. The half-life of a pollutant is the amount of time it takes for one half of the chemical to be degraded. Soluble lead compounds, such as the acetate, may decompose to insoluble sulfate or phosphate derivatives in soil where they will settle and become immobile.

🐟 *Bioaccumulation in Aquatic Organisms*

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans.

The concentration of lead found in the edible tissues of fish is expected to be much higher than the average concentration of lead found in the water from which the fish was taken.

🛑 *Recommended Risk-Reduction Measures*

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in the contamination of the environment. The correct use of DOT labeling (per the MSDS) on all containers, trucks, and rail cars will enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of lead acetate should be segregated from incompatible chemicals to minimize the risk of cross-contamination or contact. Buildings designated for storage should be equipped with appropriate fire protection systems (alarms, sprinklers, emergency lighting, portable extinguishers).

If a spill or leak to the environment has occurred, fire department, emergency response and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those trained in proper spill containment procedures. Contaminated soils should be removed and replaced with clean soil. When environmental contamination occurs, the local and/or state emergency response authorities may require notification. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of lead acetate.

For disposal, lead acetate is a poor candidate for incineration. It is suggested that it be converted to nitrates by adding a small amount of concentrated nitric acid. The mixture should then be evaporated in a fume hood to form a thin paste. Next, water (500 ml) should be added and the paste saturated with hydrogen sulfide. The resulting precipitate is lead sulfite which can be filtered, washed, and dried. Finally, the material can be packaged and sent back to a supplier for reclamation.

If lead acetate is spilled or leaked, the following specific steps are recommended:

- ☑ Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened for normal work.
- ☑ Remove all ignition sources.
- ☑ Collect powdered materials in the safest manner possible and deposit in sealed containers. Do NOT dry sweep (generates airborne dust). Use a vacuum equipped with a high-efficiency particulate air (HEPA) filter. Damp mop residues.
- ☑ It may be necessary to dispose of lead acetate as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving lead acetate can present a significant threat to business operations. The loss or damage of equipment or facilities due to explosion or fire can significantly affect fiscal viability. Lawsuits that may result from personnel injury/death, public exposures, and/or environmental contamination will also require a serious expenditure of resources. Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business. Always remember that anytime the terms "cancer," "carcinogen," or "reproductive hazard" are used, public emotion, hysteria, and ignorance can run equally high. This is also true whenever the words "lead" and "exposure" are used together. This must be carefully considered when developing or implementing public relations policy.

Recommended Risk-Reduction Measures

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures for dealing with safety or emergency response. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

SECTION I - GENERAL INFORMATION

| | | |
|---|--|------------------------------------|
| Characterization Metallic Chloride | RCRA Number None | EPA Class Not Applicable |
| DOT Proper Shipping Name Lead Chloride | Chemical Abstract Service (CAS) Number 7758-95-4 | |
| DOT Hazard Class and Label Requirements ORM-B | DOT Emergency Guide Code No Citation | |
| DOT Identification Number UN 2291 | Chemical Symbol PbCl₂ | |

Synonyms

Lead dichloride; plumbous chloride; lead (II) chloride.

SECTION II - HAZARDOUS INGREDIENTS AND IDENTITY INFORMATION

| Hazardous Components (specific identity) | OSHA Exposure Criteria | NIOSH Exposure Criteria | Immediately Dangerous to Life and Health (IDLH) | ACGIH Exposure Criteria |
|---|--|--|---|--|
| Lead chloride (derivation: Produced by the addition of hydrochloric acid or sodium chloride to a solution of a lead salt with subsequent crystallization.) | PEL (as Pb): 0.050 mg/m³ STEL: Not Established | PEL (as Pb): 0.100 mg/m³ STEL: Not Established | 700 mg/m³ (as Pb) | TLV (as Pb): 0.15 mg/m³ BEI: 50 µg(lead) per liter blood |

SECTION III - PHYSICAL AND CHEMICAL CHARACTERISTICS

| | |
|--|--|
| Boiling Point 1742°F (950°C) | Specific Gravity (H ₂ O = 1) 5.85 |
| Vapor Pressure (mm Hg) 1 at 1017°F (547°C) | Molecular Weight 278.09 |
| Vapor Density (Air = 1) 9.6 | Melting Point 934°F (501°C) |

Solubility

Soluble in cold water, more soluble in hot water. Very soluble in ammonium chloride, ammonium nitrate, and alkali hydroxides. Slightly soluble in glycerol and dilute hydrochloric acid. Insoluble in alcohol.

Appearance and Odor

White crystalline powder.

SECTION IV - FIRE AND EXPLOSION HAZARD DATA

| | |
|---|--|
| Flash Point (method used) Not Applicable | Explosive Limits in Air % by Volume LEL: N/A UEL: N/A |
| NFPA Classification Non-Combustible Solid | Autoignition Temperature Not Applicable |

Extinguishing Media

Use extinguishing agent suitable to surrounding fire. Lead chloride does not burn.

Special Fire Fighting Procedures

Poisonous gases are produced in fire. Wear self-contained breathing apparatus (SCBA) operated in positive pressure mode. If possible and without risk, move containers from fire area. Do NOT release runoff from fire fighting measures to sewers or waterways. Dike for containment and disposal.

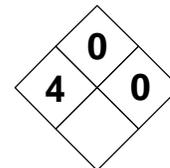

Unusual Fire and Explosion Hazards

None reported.

| SECTION V - REACTIVITY DATA | | | | |
|--|----------------------------|--|---|---|
| Stability | | Conditions to Avoid Lead chloride is normally stable under routine conditions of handling and storage. Avoid contact with heat and incompatible materials. | | |
| Stable X | Unstable | Incompatibility (materials to avoid) Lead chloride can react explosively in contact with heated calcium. | | |
| Hazardous Polymerization | | Conditions to Avoid Under normal conditions of temperature and pressure, hazardous polymerization of lead chloride will not occur. | | |
| May Occur | Will Not Occur X | Hazardous Decomposition or By-products Thermal decomposition of lead chloride will produce toxic and irritating smoke and fumes, including highly toxic fumes of lead and chloride. | | |
| SECTION VI - HEALTH HAZARD DATA | | | | |
| Primary Route(s) of Entry: | | Inhalation? X | Absorption (skin)? | Ingestion? X |
| Health Hazards INHALATION: Symptoms of lead poisoning such as headache, insomnia, persistent vomiting, blurred vision and other visual disturbances, irritability, facial pallor, pale lips, anemia, anxiety, hypertension, restlessness, delirium, hallucinations, convulsions, seizures, coma, and the appearance of a dark line along the gums in the mouth ("lead line"). SKIN & EYES: Skin and eye contact can cause irritation. INGESTION: Unlikely. If it occurs, can cause metallic taste, dry throat, abdominal pain, nausea and vomiting, diarrhea, constipation, peripheral circulatory system collapse, muscle weakness, headache, insomnia, kidney damage, coma, and death. | | | | |
| Carcinogenicity Probable Human Questioned Animal | NTP Listed? No | IARC Cancer Review Group? Group 2B | OSHA Regulated? 29 CFR 1910.1025 (Lead) | Target Organs? GI tract, blood, CNS, kidneys, gingival tissues. |
| Medical Conditions Generally Aggravated by Exposure Nervous system disorders (epilepsy), kidney diseases, hypertension, infertility, and anemia. | | | | |
| Emergency and First-aid Procedures Eye contact: Flush immediately with water for 15 minutes (minimum); seek medical attention. Skin contact: Remove all contaminated clothing. Wash contaminated skin with soap and water. For inhalation: Remove the person from exposure. Provide respiratory assistance and CPR. Transfer to medical facility. If swallowed: Never attempt to give anything by mouth to an unconscious or convulsing person. If large quantities are ingested, induce vomiting with Syrup of Ipecac and call physician. | | | | |
| SECTION VII - PRECAUTIONS FOR SAFE HANDLING AND USE | | | | |
| Steps to be Taken in Case Material is Released or Spilled Remove all sources of ignition. Restrict those not involved in cleanup from entering area. Collect powdered material in the most convenient way possible and deposit in sealed containers. Do NOT dry sweep (creates airborne dust). Use vacuum equipped with HEPA filter instead. Damp mop residue and collect for disposal. | | | | |
| Preferred Waste Disposal Method No citation. | | | | |
| Precautions to be Taken in Handling and Storage Containers should be protected against physical damage. Store in tightly closed containers in a cool, dry, well-ventilated area away from acids, caustics, heat, flame, and direct sunlight. | | | | |
| Other Precautions and Warnings Wear appropriate personal protective equipment. | | | | |
| SECTION VIII - CONTROL MEASURES AND PERSONAL PROTECTIVE EQUIPMENT | | | | |
| Respiratory Protection (specify type) Exposure level is low and difficult to monitor. Use a respirator with particulate (dust/fume/mist) filter. Otherwise use a supplied-air respirator or self-contained breathing apparatus in continuous flow mode. | | | | |
| Ventilation Local exhaust or general mechanical systems recommended. | | | | |
| Protective Gloves Suitable to protect from skin contact | | Eye Protection Chemical/Dust Goggles | | Other Protective Clothing N/A |
| Work/Hygiene Practices Always wash hands thoroughly after working with lead chloride powders and dusts; never bring food, drink, or smoking materials into vicinity of lead chloride powders. | | | | |

LEAD CHLORIDEPbCl₂

CAS: 7758-95-4

**IDENTIFICATION AND TYPICAL USES**

Lead chloride appears as a white crystalline powder. It is used in the preparation of lead salts, in pigments, paints, ceramics, in metallurgy, as a solder, flux, and as an analytical reagent.

RISK ASSESSMENT: HEALTH**General Assessment**

The toxicity of lead chloride is primarily due to lead itself. It can enter the body through *inhalation* and *ingestion*. It should be noted that ingestion poses no real toxic effect in small amounts, but repeated (chronic) ingestion can cause serious problems subsequent to lead poisoning. The IARC lists lead as a probable human carcinogen with insufficient evidence (Group 2B). Mutation data have been reported. While no specific teratogenic data are documented for the chloride, lead itself is considered a teratogen with reproductive effects also being reported.

Acute poisoning is rare, but possible by any route of exposure. Inhalation of lead and possibly its soluble salts (such as the chloride) causes acute encephalopathy with ataxia, repeated vomiting, headaches, stupor, hallucinations, tremors, convulsions or seizures, coma, and death. Other central nervous system effects include weight loss, malnutrition, restlessness, irritability, tingling in the wrists and ankles, and possible permanent brain damage. There can be kidney degradation with glomerular atrophy, interstitial fibrosis, and sclerosis of vessels. There may also be gastritis, changes in the liver, and accumulation of lead in the bones and teeth. Heavy lead intoxication can often be detected by the formation of a dark line on the gum margins (the "lead line").

Lead causes the red blood cells to become brittle and more fragile. This increased fragility of the cells allows them to be destroyed more rapidly than normal, causing anemia. Lead accumulates in bone and teeth on prolonged or repeated exposures. It has an experimental half-life in the body of 1460 days.

☠ Acute Health Effects

The following acute (short-term) health effects may occur immediately or shortly after exposure to lead:

Skin: Irritation/scratching on contact with particles.

Eye: Irritation/scratching on contact with particles.

Lung: Possible irritation of the nose, throat, and lungs following exposure to powders and dusts.

CNS: A variety of effects including stupor, hallucinations, delirium, parasthesia, headaches, convulsions and seizures, coma, and death.

☘ Chronic Health Effects

The following chronic (long-term) health effects may occur at some time after exposure to lead and can last for months or even years:

Cancer Hazards: According to information presented in the references, lead has been tested for its ability to cause cancer in test animals and the results are conflicting and inconclusive. IARC lists it as a probable human carcinogen with insufficient evidence (Group 2B). Human mutation data have been reported and many scientists believe that exposure to mutagenic compounds may pose a cancer risk in the long-term.

Reproductive Hazard: According to information presented in the references, lead has been shown to adversely affect reproduction in test animals. There may be a decreased sex drive, impotence, sterility in males, decreased fertility and abnormal menstrual cycles in females, and possible spontaneous fetal abortions in females. Unborn children may suffer neurological damage or developmental problems due to excessive lead exposures by pregnant women.

Other Chronic Effects: Long-term exposure can lead to appetite loss, nausea, metallic taste in the mouth, a dark "lead chloride line" on the gingival tissues in the mouth, constipation, anxiety, anemia, facial pallor, tiredness, weakness, insomnia, chronic headache, nervousness, irritability, tremors, tingling and numb-

ness in the extremities, muscle and joint pain, colic, abdominal pain, kidney disease, and liver damage.

☛ **Recommended Risk-Reduction Measures**

Personnel should avoid direct contact with lead chloride. *Engineering controls* are always the most effective method of reducing exposures. The best protection, especially when working with fine powders and dusts of lead chloride, is to enclose operations and/or provide explosion-proof, local exhaust ventilation at the site of powder/dust release. While not always operationally feasible, isolating operations can also reduce exposure. Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around lead chloride. The exposure level (for lead) is extremely low (0.050 mg/m^3) and difficult to accurately monitor. A respirator equipped with a dust/mist/fume filter may suffice for low or infrequent (transient) exposures. However, a supplied-air respirator operated in continuous flow mode or a self-contained breathing apparatus (SCBA) with full facepiece in pressure demand mode will provide the best respiratory protection. If a full facepiece respirator is not available, then dust goggles or safety glasses with side shields attached should be worn to protect the eyes. To prevent hand and skin exposures, suitable gloves should be used.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with lead chloride.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where lead chloride is used or stored.

Before beginning employment with lead chloride, and at regular intervals thereafter (e.g., annually), the following medical tests are recommended:

- ☑ Blood lead levels and blood pressure (baseline).
- ☑ Complete blood count (establish baseline).

If symptoms develop or overexposure is suspected, the following additional tests may be useful:

- ☑ Blood lead levels and blood pressure (compare to baseline).
- ☑ Complete blood count for microcytic anemia and basophilic stippling, blood urea nitrogen (BUN) of creatinine, and zinc protoporphyrin (ZPP).

- ☑ Examination of the central and peripheral nervous systems.
- ☑ Visual examination of the gingival gum line for the appearance of a dark "lead line" on the tissues.

Other methods to reduce exposure include:

- ☑ Where possible, enclose operations and use local exhaust ventilation at the site where lead chloride powder or dust is worked. If local exhaust ventilation or enclosure is not used, respiratory protection should be mandatory.
- ☑ Always ensure that proper protective clothing is worn when working with lead compounds.
- ☑ Wash thoroughly immediately after exposure to lead chloride and at the end of the work shift or before eating, drinking, or smoking. Clothing contaminated with lead chloride dusts or powders should not be taken home.
- ☑ Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of lead chloride should be communicated to all potentially exposed workers.
- ☑ Additional exposure control measures and engineering controls are provided by OSHA in 29 CFR 1910.1025 (Lead).

RISK ASSESSMENT: ENVIRONMENT

General Assessment

Lead occurs naturally in the environment. However, the environment is still at risk of exposure during transportation, storage, disposal, or destruction of lead chloride. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of lead chloride materials, especially the dusts and powders. Accidental contact with a variety of incompatible materials can result in fire, explosion, and possible contamination of the surrounding environmental mediums (water, soil, and, to a lesser degree, air).

Lead chloride is considered a non-combustible solid in bulk form. If its dusts and powders become airborne in sufficient quantities or in enclosed areas, there may be an explosion hazard. Lead chloride reacts explosively with calcium when heated slightly. These characteristics require special consideration during any emergency situation involving a leak or spill of lead chloride. Contact with incompatible ma-

terials can occur either during use, transportation, or storage, or disposal of lead chloride.

Lead is one of the most abundant metals in the earth's crust. It is used extensively across a broad spectrum of industries for a large variety of purpose. Because of its frequent use and common occurrence, lead enters the environment from point and non-point sources.

☠ *Acute Ecological Effects*

Acute (short-term) toxic effects may include the death of animals, birds, or fish and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to lead.

This metal has high acute toxicity to aquatic life and high toxicity to birds. Insufficient data are available on the short-term effects of lead exposure to plants or land animals.

☞ *Chronic Ecological Effects*

Chronic (long-term) toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals.

Lead has high chronic toxicity in aquatic life. Lead causes nerve and behavioral effects in humans and could cause similar long-term effects in birds and land animals. Insufficient data are available on the long-term effects of lead to plants.

💧 *Water Solubility*

Lead and its compounds range in their respective water solubilities from highly soluble to practically insoluble.

🕒 *Persistence in the Environment*

Lead is highly persistent in water, with a half-life greater than 200 days. The half-life of a pollutant is the amount of time it takes for one half of the chemical to be degraded. Soluble lead compounds, such as the chloride, may decompose to insoluble sulfate or phosphate derivatives in soil where they will settle and become immobile. Lead is expected to accumulate in aquatic and terrestrial sediments.

🐟 *Bioaccumulation in Aquatic Organisms*

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat con-

taminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans.

The concentration of lead found in the edible tissues of fish is expected to be much higher than the average concentration of lead found in the water from which the fish was taken.

🛡️ *Recommended Risk-Reduction Measures*

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in the contamination of the environment. The correct use of DOT labeling (per the MSDS) on all containers, trucks, and rail cars will enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of lead chloride should be segregated from incompatible chemicals to minimize the risk of cross-contamination or contact. Buildings designated for storage should be equipped with appropriate fire protection systems (alarms, sprinklers, emergency lighting, portable extinguishers).

If a spill or leak to the environment has occurred, fire department, emergency response and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those trained in proper spill containment procedures. Contaminated soils should be removed and replaced with clean soil. When environmental contamination occurs, the local and/or state emergency response authorities may require notification. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of lead chloride.

If lead chloride is spilled or leaked, the following specific steps are recommended:

- ☑ Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened for normal work.
- ☑ Remove all ignition sources and ventilate area.
- ☑ Collect powdered materials in the safest manner possible and deposit in sealed containers. Do NOT dry sweep (generates airborne dust). Use a vacuum equipped with a high-efficiency particulate air (HEPA) filter. Damp mop residues.
- ☑ It may be necessary to dispose of lead chloride as a hazardous waste. The responsible state agency or the regional office of the federal Environ-

mental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving lead can present a significant threat to business operations. The loss or damage of equipment or facilities due to explosion or fire can significantly affect fiscal viability. Lawsuits that may result from personnel injury/death, public exposures, and/or environmental contamination will also require a serious expenditure of resources. Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business. Always remember that anytime the terms "cancer," "carcinogen," or "reproductive hazard" are used, public emotion, hysteria, and ignorance can run equally high. This is also true whenever the words "lead" and "exposure" are used together. This must be carefully considered when developing or implementing public relations policy.

Recommended Risk-Reduction Measures

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures for dealing with safety or emergency response. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

LEAD IODIDEPbI₂

CAS: 10101-63-0

**IDENTIFICATION AND TYPICAL USES**

Lead iodide appears as a heavy, hexagonal, odorless, yellow crystals or powder. It is used in bronzing, printing, photography, cloud seeding, gold pencils, mosaic gold, in the manufacture of lead iodide film, in asbestos brake linings, in lubricating greases, in thermal batteries, and as a reagent in microchemical testing for physostigmine.

RISK ASSESSMENT: HEALTH***General Assessment***

Once absorbed into the body, lead iodide dissociates to form lead and iodide. The specific toxicity of lead iodide is primarily due to lead itself. It can enter the body through *inhalation* and *ingestion*. It should be noted that ingestion poses no real toxic effect in small amounts, but repeated (chronic) ingestion can cause serious problems subsequent to lead poisoning. While the compound lead iodide is not currently reported as carcinogenic, the IARC does list lead as a probable human carcinogen with insufficient evidence (Group 2B). Mutation data have been reported. Also, while no specific teratogenic data are documented for the iodide, lead itself is considered a teratogen with reproductive effects also being reported.

Acute poisoning is rare, but possible by both routes of exposure. Inhalation of lead and possibly its soluble salts (such as the iodide) causes acute encephalopathy with ataxia, repeated vomiting, headaches, stupor, hallucinations, tremors, convulsions or seizures, coma, and death. Other central nervous system effects include weight loss, malnutrition, restlessness, irritability, tingling in the wrists and ankles, and possible permanent brain damage. There can be kidney degradation with glomerular atrophy, interstitial fibrosis, and sclerosis of vessels. There may also be astringency, intense thirst, constipation, diarrhea, gastritis, changes in the liver, and accumulation of lead in the bones and teeth. Heavy lead intoxication can often

be detected by the formation of a dark line on the gum margins (the "lead line").

Blood complications can be severe, including anemia and hemoglobinuria (blood in urine). Lead causes the red blood cells to become brittle and more fragile. This increased fragility of the cells allows them to be destroyed more rapidly than normal, causing anemia. Lead accumulates in bone and teeth on prolonged or repeated exposures. It has an experimental half-life in the body of 1460 days.

☠ *Acute Health Effects*

The following acute (short-term) health effects may occur immediately or shortly after exposure to lead:

Skin: Irritation/scratching on contact.

Eye: Irritation/scratching on contact.

Lung: Possible irritation of the nose, throat, and lungs following exposure to powders and dusts.

CNS: A variety of effects including stupor, hallucinations, delirium, parasthesia, headaches, convulsions and seizures, coma, and death.

Other: Acute lead poisoning is rare but possible. There can be severe blood and renal system effects as well as brain effects.

☘ *Chronic Health Effects*

The following chronic (long-term) health effects may occur at some time after exposure to lead and can last for months or even years:

Cancer Hazards: According to information presented in the references, lead has been tested for its ability to cause cancer in test animals and the results are conflicting and inconclusive. IARC lists it as a probable human carcinogen with insufficient evidence (Group 2B). Human mutation data have been reported and many scientists believe that exposure to mutagenic compounds may pose a cancer risk in the long-term.

Reproductive Hazard: According to information presented in the references, lead has been shown to adversely affect reproduction in test animals. There may be a decreased sex drive, impotence, sterility in males, decreased fertility and abnormal menstrual cycles in females, and possible spontaneous fetal abortions in females. Unborn children may suffer neurological damage or developmental problems due to excessive lead exposures by pregnant women.

Other Chronic Effects: Long-term exposure can lead to appetite loss, nausea, metallic taste in the mouth, a dark "lead iodide line" on the gingival tissues in the mouth, constipation, anxiety, anemia, facial pallor, tiredness, weakness, insomnia, chronic headache, nervousness, irritability, tremors, tingling and numbness in the extremities, muscle and joint pain, colic, abdominal pain, kidney disease, and liver damage.

🕒 **Recommended Risk-Reduction Measures**

Personnel should avoid direct contact with lead iodide. *Engineering controls* are always the most effective method of reducing exposures. The best protection, especially when working with fine powders and dusts of lead iodide, is to enclose operations and/or provide explosion-proof, local exhaust ventilation at the site of powder/dust release. While not always operationally feasible, isolating operations can also reduce exposure. Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around lead iodide. The exposure level (for lead) is extremely low (0.050 mg/m^3) and difficult to accurately monitor. A respirator equipped with a dust/mist/fume filter may suffice for low or infrequent (transient) exposures. However, a supplied-air respirator operated in continuous flow mode or a self-contained breathing apparatus (SCBA) with full facepiece in pressure demand mode will provide the best respiratory protection. If a full facepiece respirator is not available, then dust goggles or safety glasses with side shields attached should be worn to protect the eyes. To prevent hand and skin exposures, suitable gloves should be used.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with lead iodide.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where lead iodide is used or stored.

Before beginning employment with lead iodide, and at regular intervals thereafter (e.g., annually), the following medical tests are recommended:

- ☑ Blood lead levels and blood pressure (baseline).
- ☑ Complete blood count (establish baseline).

If symptoms develop or overexposure is suspected, the following additional tests may be useful:

- ☑ Blood lead levels and blood pressure.
- ☑ Complete blood count for microcytic anemia and basophilic stippling, blood urea nitrogen (BUN) of creatinine, and zinc protoporphyrin (ZPP).
- ☑ Examination of the central and peripheral nervous systems.
- ☑ Visual examination of the gingival gum line for the appearance of a dark "lead line" on the tissues.

Other methods to reduce exposure include:

- ☑ Where possible, enclose operations and use local exhaust ventilation at the site where lead iodide powder or dust is worked. If local exhaust ventilation or enclosure is not used, respiratory protection should be mandatory.
- ☑ Always ensure that proper protective clothing is worn when working with lead compounds.
- ☑ Wash thoroughly immediately after exposure to lead iodide and at the end of the work shift or before eating, drinking, or smoking. Clothing contaminated with lead iodide dusts or powders should not be taken home.
- ☑ Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of lead iodide should be communicated to all exposed workers.
- ☑ Additional exposure control measures and engineering controls are provided by OSHA in 29 CFR 1910.1025 (Lead).

RISK ASSESSMENT: ENVIRONMENT

General Assessment

Lead occurs naturally in the environment. However, the environment is still at risk of exposure during transportation, storage, disposal, or destruction of lead iodide. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling

of lead iodide materials, especially the dusts and powders. Accidental contact with a variety of incompatible materials can result in fire, explosion, and possible contamination of the surrounding environmental mediums (water, soil, and, to a lesser degree, air).

Lead iodide is considered a non-combustible solid in bulk form. If its dusts and powders become airborne in sufficient quantities or in enclosed areas, there may be an explosion hazard. Lead iodide reacts with hydrogen peroxide, strong oxidizers (especially fluorine), sodium, and potassium. These characteristics require special consideration during any emergency situation involving a leak or spill of lead iodide. Contact with incompatible materials can occur either during use, transportation, or storage, or disposal of lead iodide.

Lead is one of the most abundant metals in the earth's crust. It is used extensively across a broad spectrum of industries for a large variety of purpose. Because of its frequent use and common occurrence, lead enters the environment from point and non-point sources.

☠ *Acute Ecological Effects*

Acute (short-term) toxic effects may include the death of animals, birds, or fish and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to lead.

This metal has high acute toxicity to aquatic life and high toxicity to birds. It is not expected to be taken up by plant life. Insufficient data are available on the short-term effects of lead exposure to terrestrial animals.

🕒 *Chronic Ecological Effects*

Chronic (long-term) toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals.

Lead has high chronic toxicity in aquatic life. Lead causes nerve and behavioral effects in humans and could cause similar long-term effects in birds and land animals. Insufficient data are available on the long-term effects of lead to plants.

💧 *Water Solubility*

Lead and its compounds range in their respective water solubilities from highly soluble to practically insoluble.

⌚ *Persistence in the Environment*

Lead is highly persistent in water, with a half-life greater than 200 days. The half-life of a pollutant is the amount of time it takes for one half of the chemical to be degraded. Soluble lead compounds, such as the iodide, may decompose to lead and iodide in soil where they will settle and become immobile. Lead is expected to accumulate in aquatic and terrestrial sediments. Because it absorbs in soil so well, it will not easily leach into aquatic systems nor be taken up by plant life.

🐟 *Bioaccumulation in Aquatic Organisms*

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans.

The concentration of lead found in the edible tissues of fish is expected to be much higher than the average concentration of lead found in the water from which the fish was taken.

🛡️ *Recommended Risk-Reduction Measures*

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in the contamination of the environment. The correct use of DOT labeling (per the MSDS) on all containers, trucks, and rail cars will enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of lead iodide should be segregated from incompatible chemicals to minimize the risk of cross-contamination or contact. Buildings designated for storage should be equipped with appropriate fire protection systems (alarms, sprinklers, emergency lighting, portable extinguishers).

If a spill or leak to the environment has occurred, fire department, emergency response and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those trained in proper spill containment procedures. Contaminated soils should be removed and replaced with clean soil. When environmental contamination occurs, the local and/or state emergency response authorities may require notification. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of lead iodide.

If lead iodide is spilled or leaked, the following specific steps are recommended:

- ☑ Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened for normal work.
- ☑ Remove all ignition sources and ventilate area.
- ☑ Collect powdered materials in the safest manner possible and deposit in sealed containers. Do NOT dry sweep (generates airborne dust). Use a vacuum equipped with a high-efficiency particulate air (HEPA) filter. Damp mop residues. Solution spills should be neutralized using agricultural lime, crushed lime, or sodium bicarbonate.
- ☑ It may be necessary to dispose of lead iodide as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving lead iodide can present a significant threat to business operations. The loss or damage of equipment or facilities due to explosion or fire can significantly affect fiscal viability. Lawsuits that may result from personnel injury/death, public exposures, and/or environmental contamination will also require a serious expenditure of resources. Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business. Always remember that anytime the terms "cancer," "carcinogen," or "reproductive hazard" are used, public emotion, hysteria, and ignorance can run equally high. This is also true whenever the words "lead" and "exposure" are used together. This must be carefully considered when developing or implementing public relations policy.

Recommended Risk-Reduction Measures

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures for dealing with safety or emergency response. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

| Boiling Point Decomposes | Specific Gravity (H ₂ O = 1) 4.53 |
| Vapor Pressure (mm Hg) Not Found | Molecular Weight 331.21 |
| Vapor Density (Air = 1) 11.0 | Melting Point 878°F (470°C) |

Solubility

Slightly soluble in cold water, more soluble in boiling water. Soluble in alkalis and ammonia. Insoluble in concentrated nitric acid. Slightly soluble in absolute alcohol and absolute methanol.

Appearance and Odor

White, translucent crystalline solid with no odor.

SECTION IV - FIRE AND EXPLOSION HAZARD DATA

| | |
|---|--|
| Flash Point (method used) Not Applicable | Explosive Limits in Air % by Volume LEL: Not Applicable UEL: Not Applicable |
| NFPA Classification Non-Combustible Solid | Autoignition Temperature Not Applicable |

Extinguishing Media

Use water spray (not a solid stream). Lead nitrate is non-combustible but is a powerful oxidizer. Do Not use dry chemical or carbon dioxide.

Special Fire Fighting Procedures

Poisonous gases are produced in fire. Wear self-contained breathing apparatus (SCBA) operated in positive pressure mode. If possible and without risk, move containers from fire area. Do NOT release runoff from fire fighting measures to sewers or waterways. Dike for containment and disposal.

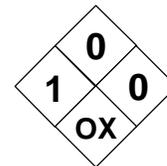

Unusual Fire and Explosion Hazards

Because it is a powerful oxidizer, lead nitrate can intensify any fire by accelerating the burning of combustible materials. Stay away from ends of tanks. Lead nitrate may explode under pressure and heat.

| SECTION V - REACTIVITY DATA | | | | |
|--|--|--|---|---|
| Stability | | Conditions to Avoid Lead nitrate is normally stable under routine conditions of handling and storage. Avoid contact with heat and incompatible materials. | | |
| Stable X | Unstable | Incompatibility (<i>materials to avoid</i>) Incompatible with ammonium thiocyanate, heated carbon, calcium-silicon alloy, cyclopentadienyl sodium, lead hypophosphite, potassium acetate + heat, hydrogen peroxide, sodium, potassium, organic materials. | | |
| Hazardous Polymerization | | Conditions to Avoid Under normal conditions of temperature and pressure, hazardous polymerization of lead nitrate will not occur. | | |
| May Occur | Will Not Occur X | Hazardous Decomposition or By-products Thermal decomposition of lead nitrate will produce toxic and irritating smoke and fumes, including highly toxic fumes of lead and nitrogen. | | |

| Primary Route(s) of Entry: | | Inhalation? X | Absorption (skin)? | Ingestion? X |
| Health Hazards INHALATION: Symptoms of lead poisoning such as headache, insomnia, persistent vomiting, blurred vision and other visual disturbances, irritability, facial pallor, pale lips, anemia, anxiety, hypertension, restlessness, delirium, hallucinations, convulsions, seizures, coma, and the appearance of a dark line along the gums in the mouth ("lead line"). SKIN & EYES: Skin and eye contact can cause irritation. INGESTION: Unlikely. If it occurs, can cause metallic taste, dry throat, abdominal pain, nausea and vomiting, diarrhea, constipation, peripheral circulatory system collapse, muscle weakness, headache, insomnia, kidney damage, coma, and death. | | | | |
| Carcinogenicity Probable Human (Pb) Questioned Animal | NTP Listed? No | IARC Cancer Review Group? Group 2B | OSHA Regulated? 29 CFR 1910.1025 (Lead) | Target Organs? GI tract, blood, CNS, kidneys, gingival tissues. |
| Medical Conditions Generally Aggravated by Exposure Nervous system disorders (epilepsy), kidney diseases, hypertension, infertility, and anemia. | | | | |
| Emergency and First-aid Procedures Eye contact: Flush immediately with water for 15 minutes (minimum); seek medical attention. Skin contact: Remove all contaminated clothing. Wash contaminated skin with soap and water. For inhalation: Remove the person from exposure. Provide respiratory assistance and CPR. Transfer to medical facility. If swallowed: Never attempt to give anything by mouth to an unconscious or convulsing person. If large quantities are ingested, induce vomiting with Syrup of Ipecac and call physician. | | | | |
| SECTION VII - PRECAUTIONS FOR SAFE HANDLING AND USE | | | | |
| Steps to be Taken in Case Material is Released or Spilled Isolate area and stay upwind. Restrict those not involved in cleanup from entering area. Collect powdered material in the most convenient way possible and deposit in sealed containers. Do NOT dry sweep (creates airborne dust). Use vacuum equipped with HEPA filter instead. Damp mop residue and collect. Neutralize solution spills with agricultural lime, crushed lime, or sodium bicarbonate. | | | | |
| Preferred Waste Disposal Method Precipitate with carbonate or sulfide, filter residue, wash, dry, package, and ship to supplier. | | | | |
| Precautions to be Taken in Handling and Storage Containers should be protected against physical damage. Store in tightly closed containers in a cool, dry, dark, well-ventilated area away from combustible materials (do not store on wooden shelves). | | | | |
| Other Precautions and Warnings Wear appropriate personal protective equipment. Keep away from heat and ignition sources. | | | | |
| SECTION VIII - CONTROL MEASURES AND PERSONAL PROTECTIVE EQUIPMENT | | | | |
| Respiratory Protection (<i>specify type</i>) Exposure level is low and difficult to monitor. Use a respirator with particulate (dust/fume/mist) filter. Otherwise use a supplied-air respirator or self-contained breathing apparatus in continuous flow mode. | | | | |
| Ventilation Local exhaust or general mechanical systems recommended. | | | | |
| Protective Gloves Suitable to protect from skin contact | Eye Protection Chemical/Dust Goggles | Other Protective Clothing N/A | | |
| Work/Hygiene Practices Always wash hands thoroughly after working with lead nitrate powders and dusts; never bring food, drink, or smoking materials into vicinity of lead nitrate powders. | | | | |

LEAD NITRATE

CAS: 10099-74-8

**IDENTIFICATION AND TYPICAL USES**

Lead nitrate is a white, translucent, odorless, crystalline solid. It is used in lead salts, as a mordant in dyeing and printing calico and for staining mother of pearl, in matches, as an oxidizer in the dye industry, a sensitizer in photography, in explosives, tanning, process engraving, and in lithography.

RISK ASSESSMENT: HEALTH**General Assessment**

The specific toxicity of lead nitrate is primarily due to lead itself. It can enter the body through *inhalation* and *ingestion*. It should be noted that ingestion poses no real toxic effect in small amounts, but repeated (chronic) ingestion or extremely large single (acute) doses can cause serious problems subsequent to lead poisoning. While the compound lead nitrate is not currently reported as carcinogenic, the IARC does list lead as a probable human carcinogen with insufficient evidence (Group 2B). Mutation data have been reported. Also, while no specific teratogenic data are documented for the nitrate, lead itself is considered a teratogen with reproductive effects also being reported.

Acute poisoning is rare, but possible by both routes of exposure. Inhalation of lead and possibly its soluble salts (such as the nitrate) causes acute encephalopathy with ataxia, repeated vomiting, headaches, stupor, hallucinations, tremors, convulsions or seizures, coma, and death. Other central nervous system effects include weight loss, malnutrition, restlessness, irritability, tingling in the wrists and ankles, and possible permanent brain damage. There can be kidney degradation with glomerular atrophy, interstitial fibrosis, and sclerosis of vessels. There may also be astringency, intense thirst, constipation, diarrhea, gastritis, changes in the liver, and accumulation of lead in the bones and teeth. Heavy lead intoxication can often be detected by the formation of a dark line on the gum margins (the "lead line").

Blood complications can be severe, including anemia and hemoglobinuria (blood in urine). Lead

causes the red blood cells to become brittle and more fragile. This increased fragility of the cells allows them to be destroyed more rapidly than normal, causing anemia. Lead accumulates in bone and teeth on prolonged or repeated exposures. It has an experimental half-life in the body of 1460 days.

☠ Acute Health Effects

The following acute (short-term) health effects may occur immediately or shortly after exposure to lead:

- Skin: Irritation/scratching on contact.
- Eye: Irritation/scratching on contact.
- Lung: Possible irritation of the nose, throat, and lungs following exposure to powders and dusts.
- CNS: A variety of effects including stupor, hallucinations, delirium, parasthesia, headaches, convulsions and seizures, coma, and death.
- Other: Acute lead poisoning is rare but possible. There can be severe blood and renal system effects as well as brain effects.

☘ Chronic Health Effects

The following chronic (long-term) health effects may occur at some time after exposure to lead and can last for months or even years:

Cancer Hazards: According to information presented in the references, lead has been tested for its ability to cause cancer in test animals and the results are conflicting and inconclusive. IARC lists it as a probable human carcinogen with insufficient evidence (Group 2B). Human mutation data have been reported and many scientists believe that exposure to mutagenic compounds may pose a cancer risk in the long-term.

Reproductive Hazard: According to information presented in the references, lead has been shown to adversely affect reproduction in test animals. There may be a decreased sex drive, impotence, low sperm count and sterility in males, decreased fertility and abnormal

menstrual cycles in females, and possible spontaneous fetal abortions in females. Unborn children may suffer neurological damage or developmental problems due to excessive lead exposures by pregnant women.

Other Chronic Effects: Long-term exposure can lead to appetite loss, nausea, metallic taste in the mouth, a dark "lead nitrate line" on the gingival tissues in the mouth, constipation, anxiety, anemia, facial pallor, tiredness, weakness, insomnia, chronic headache, nervousness, irritability, tremors, tingling and numbness in the extremities, muscle and joint pain, colic, abdominal pain, kidney disease, and liver damage.

🕒 **Recommended Risk-Reduction Measures**

Personnel should avoid direct contact with lead nitrate. *Engineering controls* are always the most effective method of reducing exposures. The best protection, especially when working with fine powders and dusts of lead nitrate, is to enclose operations and/or provide explosion-proof, local exhaust ventilation at the site of powder/dust release. While not always operationally feasible, isolating operations can also reduce exposure. Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around lead nitrate. The exposure level (for lead) is extremely low (0.050 mg/m^3) and difficult to accurately monitor. A respirator equipped with a dust/mist/fume filter may suffice for low or infrequent (transient) exposures. However, a supplied-air respirator operated in continuous flow mode or a self-contained breathing apparatus (SCBA) with full facepiece in pressure demand mode will provide the best respiratory protection. If a full facepiece respirator is not available, then dust goggles or safety glasses with side shields attached should be worn to protect the eyes. To prevent hand and skin exposures, suitable gloves should be used.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with lead nitrate.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where lead nitrate is used or stored.

Before beginning employment with lead nitrate, and at regular intervals thereafter (e.g., annually), the following medical tests are recommended:

Blood lead levels and blood pressure (baseline).

Complete blood count (establish baseline).

If symptoms develop or overexposure is suspected, the following additional tests may be useful:

Blood lead levels and blood pressure.

Complete blood count for microcytic anemia and basophilic stippling, blood urea nitrogen (BUN) of creatinine, and zinc protoporphyrin (ZPP).

Examination of the central nervous system.

Visual examination of the gingival gum line for the appearance of a dark "lead line" on the tissues.

Other methods to reduce exposure include:

Where possible, enclose operations and use local exhaust ventilation at the site where lead nitrate powder or dust is worked. If local exhaust ventilation or enclosure is not used, respiratory protection should be mandatory.

Always ensure that proper protective clothing is worn when working with lead compounds.

Wash thoroughly immediately after exposure to lead nitrate and at the end of the work shift or before eating, drinking, or smoking. Clothing contaminated with lead nitrate dusts or powders should not be taken home.

Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of lead nitrate should be communicated to all exposed workers.

Additional exposure control measures and engineering controls are provided by OSHA in 29 CFR 1910.1025 (Lead).

RISK ASSESSMENT: ENVIRONMENT

General Assessment

Lead occurs naturally in the environment. However, the environment is still at risk of exposure during transportation, storage, disposal, or destruction of lead nitrate. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of lead nitrate materials, especially the dusts and powders. Accidental contact with a variety of incompatible materials can result in fire, explosion, and possible contamination of the surrounding environmental mediums (water, soil, and, to a lesser degree, air).

Lead nitrate is considered a non-combustible solid in bulk form. If its dusts and powders become air-

borne in sufficient quantities or in enclosed areas, there may be an explosion hazard. Lead nitrate is a powerful oxidizer and can greatly accelerate the combustion of combustible materials. It can react with hydrogen peroxide, ammonium thiocyanate, calcium-silicon alloy, sodium, and potassium. It can explode in contact with heated carbon. These characteristics require special consideration during any emergency situation involving a leak or spill of lead nitrate. Contact with incompatible materials can occur either during use, transportation, or storage, or disposal of lead nitrate.

Lead is one of the most abundant metals in the earth's crust. It is used extensively across a broad spectrum of industries for a large variety of purposes. Because of its frequent use and common occurrence, lead enters the environment from point and non-point sources.

☠ *Acute Ecological Effects*

Acute (short-term) toxic effects may include the death of animals, birds, or fish and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to lead. This metal has high acute toxicity to aquatic life and high toxicity to birds. It is not expected to be taken up by plant life. Insufficient data are available on the short-term effects of lead exposure to land animals.

🕒 *Chronic Ecological Effects*

Chronic (long-term) toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals. Lead has high chronic toxicity in aquatic life. Lead causes nerve and behavioral effects in humans and could cause similar long-term effects in birds and land animals. Insufficient data are available on the long-term effects of lead to plants.

💧 *Water Solubility*

Lead and its compounds range in their respective water solubilities from highly soluble to practically insoluble.

Lead is highly persistent in water, with a half-life greater than 200 days. The half-life of a pollutant is the amount of time it takes for one half of the chemical to be degraded. Soluble lead compounds, such as

the nitrate, may decompose to lead and nitrate in soil where they will settle and become immobile. Lead is expected to accumulate in aquatic and terrestrial sediments. Because it absorbs in soil so well, it will not easily leach into aquatic systems nor be taken up by plant life.

🌊 *Bioaccumulation in Aquatic Organisms*

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans. The concentration of lead found in the edible tissues of fish is expected to be much higher than the average concentration of lead found in the water from which the fish was taken.

🛑 *Recommended Risk-Reduction Measures*

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in the contamination of the environment. The correct use of DOT labeling (per the MSDS) on all containers, trucks, and rail cars will enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of lead nitrate should be segregated from incompatible chemicals to minimize the risk of cross-contamination or contact. Buildings designated for storage should be equipped with appropriate fire protection systems (alarms, sprinklers, emergency lighting, portable extinguishers).

If a spill or leak to the environment has occurred, fire department, emergency response and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those trained in proper spill containment procedures. Contaminated soils should be removed and replaced with clean soil. When environmental contamination occurs, the local and/or state emergency response authorities may require notification. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of lead nitrate.

If lead nitrate is spilled or leaked, the following specific steps are recommended:

- ☑ Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened for normal work.

Risk Management for Hazardous Chemicals

- ☑ Remove all ignition sources and ventilate area.
- ☑ Collect powdered materials in the safest manner possible and deposit in sealed containers. Do NOT dry sweep (generates airborne dust). Use a vacuum equipped with a high-efficiency particulate air (HEPA) filter. Damp mop residues. Solution spills should be neutralized with soda ash and taken up with sand, vermiculite, or other absorbent material.
- ☑ It may be necessary to dispose of lead nitrate as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS***General Assessment***

Accidents or mishaps involving lead can present a significant threat to business operations. The loss or damage of equipment or facilities due to explosion or fire can significantly affect fiscal viability. Lawsuits that may result from personnel injury/death, public exposures, and/or environmental contamination will also require a serious expenditure of resources. Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business. Always remember that anytime the terms "cancer," "carcinogen," or "reproductive hazard" are used, public emotion, hysteria, and ignorance can run equally high. This is also true whenever the words "lead" and "exposure" are used together. This must be carefully considered when developing or implementing public relations policy.

🔗 *Recommended Risk-Reduction Measures*

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures for dealing with safety or emergency response. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

SECTION I - GENERAL INFORMATION

| | | |
|--|--|------------------------------------|
| Characterization Sulfate | RCRA Number None | EPA Class Not Applicable |
| DOT Proper Shipping Name Lead Sulfate, Solid (>3% free acid) | Chemical Abstract Service (CAS) Number 7446-14-2 | |
| DOT Hazard Class and Label Requirements ORM-E; Corrosive Material; Corrosive | DOT Emergency Guide Code No Citation | |
| DOT Identification Number UN 1794 | Chemical Symbol PbSO₄ | |

Synonyms

Angliscite; Fast White®; CI Pigment White 3®; Freemans White Lead®; lead bottoms; Milk White®; Mulhouse White®; sulfuric acid, lead (2+) salt (1:1); lead dross.

SECTION II - HAZARDOUS INGREDIENTS AND IDENTITY INFORMATION

| Hazardous Components (specific identity) | OSHA Exposure Criteria | NIOSH Exposure Criteria | Immediately Dangerous to Life and Health (IDLH) | ACGIH Exposure Criteria |
|--|--|--|---|--|
| Lead sulfate (derivation: By interaction of sodium sulfate and lead nitrate solutions). | PEL (as Pb): 0.050 mg/m³ STEL: Not Established | PEL (as Pb): 0.100 mg/m³ STEL: Not Established | 700 mg/m³ (as Pb) | TLV (as Pb): 0.15 mg/m³ BEI: 50 µg(lead) per liter blood |

SECTION III - PHYSICAL AND CHEMICAL CHARACTERISTICS

| | |
|--|--|
| Boiling Point Decomposes | Specific Gravity (H ₂ O = 1) 4.53 |
| Vapor Pressure (mm Hg) Not Found | Molecular Weight 331.21 |
| Vapor Density (Air = 1) 11.0 | Melting Point 878°F (470°C) |

Solubility

Slightly soluble in hot water. Insoluble in alcohol. Soluble in sodium hydroxide solution and concentrated hydriodic acid.

Appearance and Odor

White, rhombic, heavy crystals or powder.

SECTION IV - FIRE AND EXPLOSION HAZARD DATA

| | |
|---|--|
| Flash Point (method used) Not Applicable | Explosive Limits in Air % by Volume LEL: Not Applicable UEL: Not Applicable |
| NFPA Classification Non-Combustible Solid | Autoignition Temperature Not Applicable |

Extinguishing Media

Use extinguishing media suitable to surrounding fire. Lead sulfate does not burn.

Special Fire Fighting Procedures

Poisonous gases are produced in fire. Wear self-contained breathing apparatus (SCBA) operated in positive pressure mode. If possible and without risk, move containers from fire area. Do NOT release runoff from fire fighting measures to sewers or waterways. Dike for containment and disposal.

Unusual Fire and Explosion Hazards

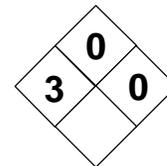

Use water spray to cool containers that cannot be moved from fire area. Stay away from ends of tanks. Lead sulfate produces toxic fumes of lead and sulfur oxides when involved in fire.

| SECTION V - REACTIVITY DATA | | | | |
|--|--|---|---|---|
| Stability | | Conditions to Avoid Lead sulfate is normally stable under routine conditions of handling and storage. Avoid contact with heat and incompatible materials. | | |
| Stable X | Unstable | Incompatibility (<i>materials to avoid</i>) Violent or explosive reactions with potassium. | | |
| Hazardous Polymerization | | Conditions to Avoid Under normal conditions of temperature and pressure, hazardous polymerization of lead sulfate will not occur. | | |
| May Occur | Will Not Occur X | Hazardous Decomposition or By-products Thermal decomposition of lead sulfate will produce toxic and irritating smoke and fumes, including highly toxic fumes of lead and sulfur oxides. | | |
| SECTION VI - HEALTH HAZARD DATA | | | | |
| Primary Route(s) of Entry: | | Inhalation? X | Absorption (skin)? | Ingestion? X |
| Health Hazards INHALATION: Symptoms of lead poisoning such as headache, insomnia, persistent vomiting, blurred vision and other visual disturbances, irritability, facial pallor, pale lips, anemia, anxiety, hypertension, restlessness, delirium, hallucinations, convulsions, seizures, coma, and the appearance of a dark line along the gums in the mouth ("lead line"). SKIN & EYES: Corrosive irritant to the skin and eyes. INGESTION: Unlikely. If it occurs, can cause metallic taste, dry throat, abdominal pain, nausea and vomiting, diarrhea, constipation, peripheral circulatory system collapse, muscle weakness, headache, insomnia, kidney damage, coma, and death. | | | | |
| Carcinogenicity Probable Human (Pb) Questioned Animal | NTP Listed? No | IARC Cancer Review Group? Group 2B | OSHA Regulated? 29 CFR 1910.1025 (Lead) | Target Organs? GI tract, blood, CNS, kidneys, gingival tissues. |
| Medical Conditions Generally Aggravated by Exposure Nervous system disorders (epilepsy), kidney diseases, hypertension, infertility, and anemia. | | | | |
| Emergency and First-aid Procedures Eye contact: Flush immediately with water for 15 minutes (minimum); seek medical attention. <u>Skin contact:</u> Remove all contaminated clothing. Wash contaminated skin with soap and water. For <u>inhalation:</u> Remove the person from exposure. Provide respiratory assistance and CPR. Transfer to medical facility. <u>If swallowed:</u> Never attempt to give anything by mouth to an unconscious or convulsing person. If large quantities are ingested, induce vomiting with Syrup of Ipecac and call physician. | | | | |
| SECTION VII - PRECAUTIONS FOR SAFE HANDLING AND USE | | | | |
| Steps to be Taken in Case Material is Released or Spilled Isolate area and stay upwind. Restrict those not involved in cleanup from entering area. Collect powdered material in the most convenient way possible and deposit in sealed containers. Do NOT dry sweep (creates airborne dust). Use vacuum equipped with HEPA filter instead. Damp mop residue and collect for disposal. | | | | |
| Preferred Waste Disposal Method No citation. | | | | |
| Precautions to be Taken in Handling and Storage Containers should be protected against physical damage. Store in tightly closed containers in a cool, dry, dark, well-ventilated area. Do not store in direct sunlight. | | | | |
| Other Precautions and Warnings Wear appropriate personal protective equipment. Keep away from heat and ignition sources. | | | | |
| SECTION VIII - CONTROL MEASURES AND PERSONAL PROTECTIVE EQUIPMENT | | | | |
| Respiratory Protection (<i>specify type</i>) Exposure level is low and difficult to monitor. Use a respirator with particulate (dust/fume/mist) filter. Otherwise use a supplied-air respirator or self-contained breathing apparatus in continuous flow mode. | | | | |
| Ventilation Local exhaust or general mechanical systems recommended. | | | | |
| Protective Gloves Suitable to protect from skin contact | Eye Protection Chemical/Dust Goggles | Other Protective Clothing N/A | | |
| Work/Hygiene Practices Always wash hands thoroughly after working with lead sulfate powders and dusts; never bring food, drink, or smoking materials into vicinity of lead sulfate powders. | | | | |

LEAD SULFATE

PbSO₄

CAS: 7446-14-2

IDENTIFICATION AND TYPICAL USES

Lead sulfate is a white, heavy, rhombic, crystalline solid. It is used in storage batteries, paint pigments (whites), lithography, in the manufacture of minium, in weighting fabrics, and in the preparation of rapidly drying oil-based varnishes.

RISK ASSESSMENT: HEALTH

General Assessment

The specific toxicity of lead sulfate is primarily due to lead itself. It can enter the body through *inhalation* and *ingestion*. It is also extremely corrosive to skin and eye tissues, but dermal absorption has not been reported. It should be noted that ingestion poses no real toxic effect in small amounts, but repeated (chronic) ingestion or extremely large single (acute) doses can cause serious problems subsequent to lead poisoning. While the compound lead sulfate is not currently reported as carcinogenic, the IARC does list lead as a probable human carcinogen with insufficient evidence (Group 2B). Mutation data have been reported. Also, while no specific teratogenic data are documented for the sulfate, lead itself is considered a teratogen with reproductive effects also being reported.

Acute poisoning is rare, but possible by both routes of exposure. Inhalation of lead and possibly its soluble salts (such as the sulfate) causes acute encephalopathy with ataxia, repeated vomiting, headaches, stupor, hallucinations, tremors, convulsions or seizures, coma, and death. Other central nervous system effects include weight loss, malnutrition, restlessness, irritability, tingling in the wrists and ankles, and possible permanent brain damage. There can be kidney degradation with glomular atrophy, interstitial fibrosis, and sclerosis of vessels. There may also be astringency, intense thirst, constipation, diarrhea, gastritis, changes in the liver, and accumulation of lead in the bones and teeth. Heavy lead intoxication can often be detected by the formation of a dark line on the gum margins (the "lead line").

Blood complications can be severe, including anemia and hemoglobinuria (blood in urine). Lead causes the red blood cells to become brittle and more fragile. This increased fragility of the cells allows them to be destroyed more rapidly than normal, causing anemia. Once it enters the body, lead circulates to various organs and then settles and accumulates in bone and teeth on prolonged or repeated exposures. It has an experimental half-life in the body of 1460 days.

☠ *Acute Health Effects*

The following acute (short-term) health effects may occur immediately or shortly after exposure to lead:

- Skin: Irritation and possible corrosive destruction.
- Eye: Corrosive to eye tissues. It may cause damage to vision on prolonged contact.
- Lung: Possible irritation of the nose, throat, and lungs following exposure to powders and dusts.
- CNS: A variety of effects including stupor, hallucinations, delirium, parasthesia, headaches, convulsions and seizures, coma, and death.
- Other: Acute lead poisoning is rare but possible. There can be severe blood and renal system effects as well as brain effects. Lead-induced anemia and its subsequent effects on blood pressure can seriously aggravate existing cardiovascular diseases.

●* *Chronic Health Effects*

The following chronic (long-term) health effects may occur at some time after exposure to lead and can last for months or even years:

Cancer Hazards: According to information presented in the references, lead has been tested for its ability to cause cancer in test animals and the results are conflicting and inconclusive. IARC lists it as a probable human carcinogen with insufficient evidence (Group 2B). Human mutation data have been reported and

many scientists believe that exposure to mutagenic compounds may pose a cancer risk in the long-term.

Reproductive Hazard: According to information presented in the references, lead has been shown to adversely affect reproduction in test animals. There may be a decreased sex drive, impotence, low sperm count and sterility in males, decreased fertility and abnormal menstrual cycles in females, and possible spontaneous fetal abortions in females. Unborn children may suffer neurological damage or developmental problems due to excessive lead exposures by pregnant women.

Other Chronic Effects: Long-term exposure can lead to appetite loss, nausea, metallic taste in the mouth, a dark "lead sulfate line" on the gingival tissues in the mouth, constipation, anxiety, anemia, facial pallor, tiredness, weakness, insomnia, chronic headache, nervousness, irritability, tremors, tingling and numbness in the extremities, muscle and joint pain, colic, abdominal pain, kidney disease, and liver damage.

☉ **Recommended Risk-Reduction Measures**

Personnel should avoid direct contact with lead sulfate. *Engineering controls* are always the most effective method of reducing exposures. The best protection, especially when working with fine powders and dusts of lead sulfate, is to enclose operations and/or provide explosion-proof, local exhaust ventilation at the site of powder/dust release. While not always operationally feasible, isolating operations can also reduce exposure. Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around lead sulfate. The exposure level (for lead) is extremely low (0.050 mg/m^3) and difficult to accurately monitor. A respirator equipped with a dust/mist/fume filter may suffice for low or infrequent (transient) exposures. However, a supplied-air respirator operated in continuous flow mode or a self-contained breathing apparatus (SCBA) with full facepiece in pressure demand mode will provide the best respiratory protection. If a full facepiece respirator is not available, then dust goggles or safety glasses with side shields attached should be worn to protect the eyes. To prevent hand and skin exposures, suitable gloves should be used. Glove manufacturers should be contacted for glove permeation studies.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with lead sulfate.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where lead sulfate is used or stored.

Before beginning employment with lead sulfate, and at regular intervals thereafter (e.g., annually), the following medical tests are recommended:

- Blood lead levels and blood pressure (baseline).
- Complete blood count (establish baseline).

If symptoms develop or overexposure is suspected, the following additional tests may be useful:

- Blood lead levels and blood pressure.
- Complete blood count for microcytic anemia and basophilic stippling, blood urea nitrogen (BUN) of creatinine, and zinc protoporphyrin (ZPP).
- Examination of the central nervous system.
- Visual examination of the gingival gum line for the appearance of a dark "lead line" on the tissues.

Other methods to reduce exposure include:

- Where possible, enclose operations and use local exhaust ventilation at the site where lead sulfate powder or dust is worked. If local exhaust ventilation or enclosure is not used, respiratory protection should be mandatory.
- Always ensure that proper protective clothing is worn when working with lead compounds.
- Wash thoroughly immediately after exposure to lead sulfate and at the end of the work shift or before eating, drinking, or smoking. Clothing contaminated with lead sulfate dusts or powders should not be taken home.
- Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of lead sulfate should be communicated to all exposed workers.
- Additional exposure control measures and engineering controls are provided by OSHA in 29 CFR 1910.1025 (Lead).

RISK ASSESSMENT: ENVIRONMENT

General Assessment

Lead occurs naturally in the environment. However, the environment is still at risk of exposure during transportation, storage, disposal, or destruction of lead sulfate. In almost every scenario, the threat of envi-

ronmental exposure is contingent upon the proper handling of lead sulfate materials, especially the dusts and powders. Accidental contact with a variety of incompatible materials can result in fire, explosion, and possible contamination of the surrounding environmental mediums (water, soil, and, to a lesser degree, air).

Lead sulfate is considered a non-combustible solid in bulk form. If its dusts and powders become airborne in sufficient quantities or in enclosed areas, there may be an explosion hazard. Lead sulfate can explode in contact with potassium. These characteristics require special consideration during any emergency situation involving a leak or spill of lead sulfate. Contact with incompatible materials can occur either during use, transportation, or storage, or disposal of lead sulfate.

Lead is one of the most abundant metals in the earth's crust. It is used extensively across a broad spectrum of industries for a large variety of purpose. Because of its frequent use and common occurrence, lead enters the environment from point and non-point sources.

☠ *Acute Ecological Effects*

Acute (short-term) toxic effects may include the death of animals, birds, or fish and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to lead. This metal has high acute toxicity to aquatic life and high toxicity to birds. It is not expected to be taken up by plant life. Insufficient data are available on the short-term effects of lead exposure to land animals.

🌱 *Chronic Ecological Effects*

Chronic (long-term) toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals. Lead has high chronic toxicity in aquatic life. Lead causes nerve and behavioral effects in humans and could cause similar long-term effects in birds and land animals. Insufficient data are available on the long-term effects of lead to plants.

💧 *Water Solubility*

Lead sulfate is slightly soluble in water, depending upon water temperature. Concentrations between 1 and 100 milligrams will mix with a liter of water.

🕒 *Persistence in the Environment*

Lead is highly persistent in water, with a half-life greater than 200 days. The half-life of a pollutant is the amount of time it takes for one half of the chemical to be degraded. Soluble lead compounds, such as the sulfate, may decompose to lead and sulfate in soil where they will settle and become immobile. Lead is expected to accumulate in aquatic and terrestrial sediments. Because it absorbs in soil and forms complexes with resident organic matter, it will not easily leach into aquatic systems nor be taken up by plant life.

🐟 *Bioaccumulation in Aquatic Organisms*

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans. The concentration of lead found in the edible tissues of fish is expected to be much higher than the average concentration of lead found in the water from which the fish was taken.

🛑 *Recommended Risk-Reduction Measures*

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in the contamination of the environment. The correct use of DOT labeling (per the MSDS) on all containers, trucks, and rail cars will enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of lead sulfate should be segregated from incompatible chemicals to minimize the risk of cross-contamination or contact. Buildings designated for storage should be equipped with appropriate fire protection systems (alarms, sprinklers, emergency lighting, portable extinguishers).

If a spill or leak to the environment has occurred, fire department, emergency response and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those trained in proper spill containment procedures. Contaminated soils should be removed and replaced with clean soil. When environmental contamination occurs, the local and/or state emergency response authorities may require notification. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of lead sulfate.

If lead sulfate is spilled or leaked, the following specific steps are recommended:

- ☑ Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened for normal work.
- ☑ Remove all ignition sources and ventilate area.
- ☑ Collect powdered materials in the safest manner possible and deposit in sealed containers. Do NOT dry sweep (generates airborne dust). Use a vacuum equipped with a high-efficiency particulate air (HEPA) filter. Damp mop residues.
- ☑ It may be necessary to dispose of lead sulfate as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving lead sulfate can present a significant threat to business operations. The loss or damage of equipment or facilities due to explosion or fire can significantly affect fiscal viability. Lawsuits that may result from personnel injury/death, public exposures, and/or environmental contamination will also require a serious expenditure of resources. Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business. Always remember that anytime the terms "cancer," "carcinogen," or "reproductive hazard" are used, public emotion, hysteria, and ignorance can run equally high. This is also true whenever the words "lead" and "exposure" are used together. This must be carefully considered when developing or implementing public relations policy.

Recommended Risk-Reduction Measures

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures for dealing with safety or emergency response. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

| Stability | | Conditions to Avoid Lindane can decompose slowly at ordinary pH of 7 and more rapidly under alkaline conditions. Avoid exposure to high temperatures or incompatible materials. | | |
| Stable X | Unstable | Incompatibility (materials to avoid) Lindane is decomposed by alkalis to form trichlorobenzenes and reacts with powdered aluminum, iron, and zinc. It is corrosive to metals. | | |
| Hazardous Polymerization | | Conditions to Avoid Under normal conditions of temperature and pressure, hazardous polymerization of lindane is not known to occur. | | |
| May Occur | Will Not Occur X | Hazardous Decomposition or By-products At high temperatures, lindane decomposes and may produce poisonous gases, including toxic carbon oxides, chlorine, hydrogen chloride, and phosgene gas. | | |
| SECTION VI - HEALTH HAZARD DATA | | | | |
| Primary Route(s) of Entry: | Inhalation? X | Absorption (skin/eye)? X | Ingestion? X | |
| Health Hazards INHALATION: Breathing dusts can cause irritation of the nose and throat. Repeated contact will lead to toxic systemic effects. These include headache, dizziness, nausea, vomiting, malaise, profuse sweating, fatigue, clonic or tonic convulsions, myoclonic limb jerks, coma, and respiratory failure. May cause tremors, fainting, muscle spasms, weight loss, and damage to the liver and kidneys. ABSORPTION: Irritation and possible sensitization. Solution can pass through intact skin to cause toxic effects similar to inhalation. Absorption coupled with other exposures can be fatal. INGESTION: Nausea, vomiting, diarrhea, and systemic effects (see inhalation). | | | | |
| Carcinogenicity Questioned Human Questioned Animal | NTP Listed? 5th Annual Report | IARC Cancer Review Group? Group 2B | OSHA Regulated? 29 CFR 1910.1000 Table Z-1 | Target Organs? CNS, liver, kidneys, eyes, skin, resp. system, blood. |
| Medical Conditions Generally Aggravated by Exposure Central nervous system disorders (seizures) and kidney or liver diseases may be aggravated. | | | | |
| Emergency and First-aid Procedures Eye contact: Do not allow victim to keep eyes tightly shut. Flush immediately with water for 15 minutes; seek medical attention. Skin contact: Remove all contaminated clothing. Immediately wash area with flooding amounts of water. If red skin or blisters appear, seek medical assistance. Inhalation: Remove the person from exposure. Provide respiratory assistance and CPR. Transfer to medical facility. If swallowed: Contact poison control center. Unless advised otherwise, give 1-2 glasses of water. The decision to induce vomiting should be made on a case-by-case bases because of the possibility of seizures. Never give anything by mouth to an unconscious or convulsing person. | | | | |
| SECTION VII - PRECAUTIONS FOR SAFE HANDLING AND USE | | | | |
| Steps to be Taken in Case Material is Released or Spilled Remove all sources of ignition. Ventilate area of spill. Restrict those not involved in cleanup from entering area. Notify appropriate authorities. Carefully scoop or collect powdered materials with a vacuum equipped with HEPA filter (do NOT generate dusts). Dispose of in sealed drums. | | | | |
| Preferred Waste Disposal Method Rotary kiln incineration is recommended. | | | | |
| Precautions to be Taken in Handling and Storage Store in tightly closed containers in cool, well-ventilated area away from heat and incompatibilities. | | | | |
| Other Precautions and Warnings Avoid generating dusts. Do not store near powdered aluminum, iron, or zinc. | | | | |
| SECTION VIII - CONTROL MEASURES AND PERSONAL PROTECTIVE EQUIPMENT | | | | |
| Respiratory Protection (specify type) For exposures above 0.5 mg/m³, use a NIOSH-approved chemical respirator. Better protection is obtained using a supplied-air respirator or a SCBA with full facepiece operated in positive pressure mode. | | | | |
| Ventilation Local exhaust (preferred) at site of chemical work or general ventilation. | | | | |
| Protective Gloves Polycarbonate or Butyl Rubber | Eye Protection Chemical/Dust Goggles or Face Mask | Other Protective Clothing Protective Apron, Boots (avoid skin contact) | | |
| Work/Hygiene Practices Always wash hands thoroughly after using chemical; never bring food, drink, or smoking materials into vicinity of chemicals. | | | | |

LINDANE

CAS: 58-89-9

**IDENTIFICATION AND TYPICAL USES**

Lindane is a white to yellow, crystalline powder with a slight musty odor. It is used as an insecticide and pesticide for controlling insects in wood, cotton, and other foliar plants. It is also used in the treatment of vegetable and fruit seeds and for controlling termites. Weak solution (1%) may be used to kill lice and mites on the human body. Its use may be restricted in some areas.

RISK ASSESSMENT: HEALTH**General Assessment**

Lindane is highly toxic to humans by all routes of exposure (*inhalation, ingestion, and skin absorption*). It is a questionable carcinogen in animals and in humans, with experimental teratogenic and mutagenic data also reported. Because of the chemical's long persistence in the environment, unknown exposures can occur through contact with contaminated soils, water, and vegetation, at hazardous waste sites, or contaminated manufacturing sites. Should human exposure ever occur, lindane can cause serious toxic and poisonous systemic effects up to and including death.

Lindane is a central nervous system stimulant. Symptoms of exposure by both inhalation and skin contact (absorption) include respiratory depression with convulsions, hypersalivation, hyperirritability, profuse sweating, myoclonic limb jerks, clonic/tonic convulsions, and coma. There may also be headache, dizziness, fatigue, blurred vision, tremors, and respiratory failure. Inhalation also causes irritation of the eyes, nose, and throat. Skin absorption may produce greater toxicity than inhalation. Combined exposures (e.g., inhalation *and* absorption) are extremely dangerous and can lead to death in some cases. Caution is therefore warranted when inhalation and skin contact exposures are possible. Even though air levels may be

within limits, personnel may be overexposed if lindane should contact the skin.

In addition to absorption and subsequent systemic effects, skin contact will result in moderate to severe irritation. Eye contact may also result in irritation. The chemical may even be absorbed through direct eye contact. Ingestion causes nausea, vomiting, diarrhea, and systemic effects of inhalation and skin absorption.

☠ Acute Health Effects

The following acute (short-term) health effects may occur immediately or shortly after exposure to lindane:

- Skin:** Liquid can pass through unbroken skin. Contact may cause irritation and rash. Symptoms of exposure include headache, nausea, abdominal pain, vomiting, and CNS stimulation.
- Eye:** Mild to severe irritation. Absorption through direct eye contact is possible.
- Lung:** Irritation of the nose and throat. Breathing dusts or solution vapors can cause cough, convulsions, and adverse effects on the liver.
- CNS:** A central nervous system stimulant. Symptoms include, irritability, blurred vision, tremors, convulsions, and mental confusion.

☘ Chronic Health Effects

The following chronic (long-term) health effects may occur at some time after exposure to lindane and can last for months or even years:

Cancer Hazards: Lindane may be a carcinogen in humans since it has been shown to cause cancer in animals. Mutation data have also been reported and many scientists believe that exposure to such chemicals may pose a cancer risk in the long-term. Further research is required in this regard.

Reproductive Hazard: There is some evidence that exposure to lindane causes damage to the developing fetus in test animals. Lindane may decrease fertility in males and females.

Other Chronic Effects: Repeated exposures may lead to chronic fainting, muscle spasms, tremors, and weight loss. Lindane is stored primarily in the fatty tissues and remains relatively unchanged.

🕒 **Recommended Risk-Reduction Measures**

Personnel should avoid direct contact with lindane. If a less toxic material or compound cannot be substituted for lindane, then *engineering controls* are the most effective method of reducing exposures. The best protection is to enclose operations and/or provide local exhaust ventilation at the site of lindane dust release. This may be practical in manufacturing operations, but is not feasible in application since it is primarily used outdoors. While not always operationally possible, isolating operations involving lindane manufacturing can also reduce exposure. Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around lindane. The PEL is extremely low (0.5 mg/m^3) and difficult to accurately monitor. For low or infrequent exposures, a chemical cartridge respirator equipped with a dust/mist pre-filter may suffice. For higher or prolonged exposures, or exposures to unknown levels (as in an emergency), an MSHA or NIOSH-approved supplied-air respirator operated in continuous flow or a self-contained breathing apparatus (SCBA) with full facepiece operated in positive pressure mode are recommended for the greatest possible respiratory protection. If a full facepiece is not available, then chemical goggles should be worn to protect the eyes. A face shield and protective apron should also be worn. To prevent hand and skin exposures, impervious gloves should be used. Polycarbonate or butyl rubber may provide the best protection. Glove manufacturers should be contacted and permeation studies obtained *before* final glove selections have been made.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with lindane.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where lindane is used or stored.

If symptoms develop or overexposure is suspected, the following medical testing may be useful:

- ☑ Liver and kidney function tests.
- ☑ Urinalysis for halogenated compounds.
- ☑ Neurological evaluation of central nervous system functions. Precautions against seizures should be taken in the event of acute overexposure.
- ☑ Complete blood count to include white blood count, red blood count and differential.

Any evaluation should include a careful history of past and present symptoms with an examination. Medical tests that simply look for existing damage are not a substitute for controlling exposures.

Other methods to reduce exposure include:

- ☑ Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not used, respiratory protection should be mandatory.
- ☑ Always ensure that proper protective clothing is worn when using chemical substances and that personnel are trained in its use and care.
- ☑ Wash thoroughly immediately after exposure to lindane and at the end of the work shift or before eating, drinking, or smoking.
- ☑ Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of lindane should be communicated to all potentially exposed workers.
- ☑ Eye wash stations should be provided in the immediate work area for emergency use. If there is a possibility of skin exposure to lindane, emergency shower facilities should also be provided.
- ☑ Workers whose clothing has been contaminated by lindane should change into clean clothes before leaving work. Contaminated work clothing should be laundered only by individuals who have been informed of the hazards of exposure to lindane.
- ☑ Specific engineering controls are recommended by NIOSH. Refer to NIOSH Criteria Document: Occupational Exposure During the Manufacture and Formulation of Pesticides (Publication Number 78-174).

RISK ASSESSMENT: ENVIRONMENT

General Assessment

Because of its use as an insecticide and pesticide, lindane may be present in the environment. The environment is also at risk of exposure during transportation, storage, disposal, or destruction of lindane. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance. Accidental spills, large or small, where lindane contacts incompatible commodities can result in violent and even explosive reactions (depending upon conditions of spill), and possible contamination of the surrounding environmental mediums (water, soil, and air).

Lindane is considered a non-combustible solid. However, it is common practice to mix it with some flammable liquids such as benzene or xylene. Also, because it is incompatible with many alkalis, as well as some powdered metals, extreme caution is required in handling, storage, transportation, and disposal of lindane. These characteristics also require special consideration during any emergency situation involving a leak or spill of lindane powder or solutions.

Lindane may enter the environment in agricultural run off or through spills.

☠ *Acute Ecological Effects*

Acute (short-term) toxic effects may include the death of animals, birds, or fish and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to lindane. Lindane has high acute toxicity to aquatic life and to birds. Insufficient data are available on the short-term effects of lindane to plants or land animals.

🕒 *Chronic Ecological Effects*

Chronic (long-term) toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals. Lindane has high chronic toxicity to aquatic life. Insufficient data are available to evaluate or predict the long-term effects of lindane to birds, plants, or land animals.

💧 *Water Solubility*

Lindane is moderately soluble in water. Concentrations of 1 to 1000 milligrams will mix with a liter of water.

🕒 *Persistence in the Environment*

Lindane is moderately persistent in the water, with a half-life between 20 and 200 days. The half-life of a

pollutant is the amount of time it takes for one-half of the chemical to be degraded. Lindane is more persistent in dry, sandy soils than in moist soils. It can leach to ground water and absorb in terrestrial and aquatic sediments. About 52.3% of lindane will eventually end up in water; approximately 22% will end up in aquatic sediments; and about 2.3% will end up in air.

🐟 *Bioaccumulation in Aquatic Organisms*

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans.

The concentration of lindane found in fish tissues is expected to be somewhat higher than the average concentration of lindane in the water from which the fish was taken.

🛡️ *Recommended Risk-Reduction Measures*

Environmental contamination involving lindane can pose a serious, long-lasting impact on affected ecosystems. This is based upon its persistence in the environment and the fact that it can be present in contaminated soils, at hazardous waste sites, and in some stockpiles awaiting destruction.

Storage of lindane should be segregated from incompatible materials to minimize the risk of cross-contamination or contact. Buildings or storage areas should be equipped with appropriate fire protection systems (alarms, sprinklers). Proper ventilation and protective equipment should be used while handling the powders or while preparing aqueous solutions.

If a spill or leak to the environment has occurred, fire department, emergency response and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those trained in proper spill containment procedures. If lindane should contact the water table, aquifer, or navigable waterway, reclamation procedures should be initiated as soon as practical. It is nearly insoluble in water and total remediation may be possible. The local and/or state emergency response authorities must be notified. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of lindane. If lindane is spilled or leaked, the following specific steps are recommended:

Risk Management for Hazardous Chemicals

- ☑ Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened for normal work.
- ☑ Remove all ignition sources and ventilate area.
- ☑ Collect solids using a HEPA vacuum to avoid the generation of dusts. Do NOT dry sweep. Damp mop any residues and collect for disposal.
- ☑ It may be necessary to dispose of lindane as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving lindane can present a significant threat to business operations. The loss or damage of equipment or facilities can significantly affect fiscal viability. Lawsuits that may result from personnel injury/death, public exposures, and/or environmental contamination will also require a serious expenditure of resources. Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business. Always remember that anytime the terms “cancer,” “carcinogen,” or “reproductive hazard” are used, public emotion, hysteria, and ignorance can run equally high. This must be a consideration when developing public relations policies.

Recommended Risk-Reduction Measures

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures for responding to chemical incidents. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

LITHIUM

Li

CAS: 7439-93-2

**IDENTIFICATION AND TYPICAL USES**

Lithium is a soft, silvery-white alkali metal that turns yellow on exposure to air. It can exist as ingots, wire, ribbon, pellets, or rods. Lithium is metallic element of atomic number 3, group IA of the periodic table, atomic weight 6.941, valance of 1, with two stable isotopes. It is the least reactive of the alkali metals and the lightest solid element. It is used in the production of tritium, in reducing and hydrogenating agents, in alloy hardeners, and certain pharmaceuticals (psychoactive drugs for treatment of manic depression). It is a scavenger for stainless steel and mild steels in the molten state. It is used as a deodorizer in copper and copper alloys, as a catalyst, in storage batteries, rocket propellants, silver solders, and a nuclear reactor coolant.

RISK ASSESSMENT: HEALTH***General Assessment***

Lithium is primarily toxic through *inhalation* and skin contact (although dermal absorption has not been reported). *Ingestion* is also possible but is not considered a likely exposure route. There are no reports regarding its carcinogenic or mutagenic effects. Teratogenic effects have been documented.

Inhalation can cause nausea, vomiting, severe abdominal pain, diarrhea (possibly bloody), weakness and fatigue, dehydration, intense thirst, and dry mouth. Primary effects of exposure appear to be its toxic action on the central nervous system. These include tremors of the hands, sleepiness, vertigo, increased urine volume, apathy, anorexia, fatigue, incoordination, giddiness, tinnitus, slurred speech, blurred vision, light-sensitivity, possible temporary blindness, lethargy, muscular weakness, hyperactive reflexes, muscular weakness and twitching, stupor, and changes in electrocardiogram (EKG) readings. Long-term exposures can lead to hypothyroidism, leukocytosis, edema, weight gain, polydipsia (increased water intake) leading to polyuria (increase urinary output), memory impairment, epileptic seizures, kidney dam-

age, shock, hypotension, cardiac arrhythmia, coma, and death.

Lithium can react with the moisture on the skin or in the eyes to produce corrosive hydroxide causing serious burns and tissue damage. While ingestion is not considered a likely exposure route, it can cause serious kidney injury and possible CNS effects.

☠ *Acute Health Effects*

The following acute (short-term) health effects may occur immediately or shortly after exposure to lithium:

Skin: Irritation, burning, and corrosive destruction of tissues on contact. Extent of damage is contingent on moisture content on skin's surface.

Eye: Irritation and burning on contact. Water content in eyes will produce corrosive hydroxide which can seriously damage eye tissues and may cause temporary blindness.

Lung: Possible irritation of the nose, throat, and lungs following exposure to lithium dusts.

CNS: Broad range of serious and possibly life-threatening effects resulting from central nervous system depression, including death.

☘ *Chronic Health Effects*

The following chronic (long-term) health effects may occur at some time after exposure to lithium and can last for months or even years:

Cancer Hazards: According to information presented in the references, lithium has not been shown to cause cancer in test animals. It is not known if long-term exposure will lead to carcinogenic effects in humans.

Reproductive Hazard: According to information presented in the references, lithium may have some adverse effects on the developing fetus. It has been suggested that pregnant women and those breast feeding their infants avoid contact with lithium.

Other Chronic Effects: Long-term exposure to lithium can lead to chronic nervous system disorders. It can also cause kidney dysfunction and injury. Goiter has occurred in patients treated with lithium.

🔊 **Recommended Risk-Reduction Measures**

Personnel should avoid direct contact with lithium. *Engineering controls* are always the most effective method of reducing exposures. The best protection, especially when working with fine powders and dusts of lithium, is to enclose operations and/or provide explosion-proof, local exhaust ventilation at the site of powder/dust release. While not always operationally feasible, isolating operations can also reduce exposure. Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around lithium. No exposure levels have been established for lithium. However, this does not mean that exposure is without risk. For low or transient exposures, an MSHA/NIOSH-approved respirator equipped with a dust/mist pre-filter may provide adequate protection. Better protection is obtained using a self-contained breathing apparatus (SCBA) with full facepiece operated in pressure demand or a supplied-air respirator. If a full facepiece respirator is not available, then dust goggles or safety glasses with side shields attached should be worn to protect the eyes. To prevent hand and skin exposures, suitable gloves should be used.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with lithium.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where lithium is used or stored.

If symptoms develop or overexposure is suspected, the following tests might be considered:

- ☑ Complete blood count.
- ☑ Kidney function tests, including urinalysis.
- ☑ Electrocardiogram (EKG) for abnormal arrhythmia and other irregularities.
- ☑ Nervous system evaluation.

Other methods to reduce exposure include:

- ☑ Where possible, enclose operations and use local exhaust ventilation at the site where lithium powder or dust is worked. If local exhaust ven-

tilation or enclosure is not used, respiratory protection should be mandatory.

- ☑ Always ensure that proper protective clothing is worn when working with lithium compounds.
- ☑ Wash thoroughly immediately after exposure to lithium and at the end of the work shift or before eating, drinking, or smoking. Clothing contaminated with lithium dusts or powders should not be taken home.
- ☑ Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of lithium should be communicated to all potentially exposed workers.

RISK ASSESSMENT: ENVIRONMENT

General Assessment

The environment is at risk of exposure during transportation, storage, disposal, or destruction of lithium. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of lithium materials, especially the dusts and powders. Accidental contact with a variety of incompatible materials can result in fire, explosion, and possible contamination of the surrounding environmental mediums (water, soil, and, to a lesser degree, air).

Lithium is considered a flammable solid. It is incompatible with a number of commonly encountered materials, including water and air. When heated to the molten state, it is highly reactive with ordinary inert materials such as sand, cement, and ceramics. These characteristics require special consideration during any emergency situation involving a leak or spill of lithium. Should lithium ever come into contact with incompatible substances such as acids, halogenated compounds, or other reactive metals either during use, transportation, or storage, the formation of highly explosive commodities is extremely possible.

Lithium can enter the environment through spills and industrial waste discharges.

☠ ***Acute Ecological Effects***

Acute (short-term) toxic effects may include the death of animals, birds, or fish and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to lithium.

Insufficient data are available on the short-term effects of lithium exposure to aquatic life, plants, birds, or land animals.

☼ *Chronic Ecological Effects*

Chronic (long-term) toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals.

Insufficient data are available on the long-term effects of lithium to aquatic life, plants, birds, or land animals.

💧 *Water Solubility*

Lithium is not soluble in water. It reacts and decomposes to form lithium hydroxide and free hydrogen gas, which is explosive.

⌚ *Persistence in the Environment*

Lithium is non-persistent in water, with a half-life of less than 2 days. The half-life of a pollutant is the amount of time it takes for one half of the chemical to be degraded.

🐟 *Bioaccumulation in Aquatic Organisms*

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans.

Lithium will not accumulate in fish tissues.

🛡️ *Recommended Risk-Reduction Measures*

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in the contamination of the environment. The correct use of DOT labeling (per the MSDS) on all containers, trucks, and rail cars will enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of lithium should be segregated from incompatible chemicals to minimize the risk of cross-contamination or contact. It should be stored under mineral oil, kerosene or other liquid free of water and air. Buildings designated for storage should be properly equipped with appropriate fire protection systems (alarms, sprinklers, emergency lighting, portable extinguishers).

If a spill or leak to the environment has occurred, fire department, emergency response and/or hazardous

materials spill personnel should be notified immediately. Cleanup should be attempted only by those trained in proper spill containment procedures using non-sparking tools. Contaminated soils should be removed and replaced with clean soil. When environmental contamination occurs, the local and/or state emergency response authorities may require notification. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of lithium. If lithium is spilled or leaked, the following specific steps are recommended:

- ☑ Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened for normal work.
- ☑ Remove all ignition sources.
- ☑ Collect powdered materials in the safest manner possible and deposit in sealed containers. Do NOT dry sweep (generates airborne dusts). Use a vacuum equipped with a high-efficiency particulate air (HEPA) filter. Use non-sparking tools and keep water away.
- ☑ It may be necessary to dispose of lithium as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving lithium can present a significant threat to business operations. The loss or damage of equipment or facilities due to explosion or fire can significantly affect fiscal viability. Lawsuits that may result from personnel injury/death, public exposures, and/or environmental contamination will also require a serious expenditure of resources. Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business.

🛡️ *Recommended Risk-Reduction Measures*

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures dealing with safety or emergency response. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate

plans and policies should be developed, approved, and implemented long before any need for such arises.

| Emergency and First-aid Procedures | | | | |
| Eye contact: Flush immediately with water for 15 minutes (minimum); seek medical attention. Skin contact: Remove all contaminated clothing. Wash contaminated skin with soap and water. For inhalation: Remove the person from exposure. Provide respiratory assistance and CPR. Transfer to medical facility. If swallowed: Give 1 to 2 glasses of water and induce vomiting. Never attempt to give anything by mouth to an unconscious or convulsing person. Seek medical attention immediately. | | | | |
| SECTION VII - PRECAUTIONS FOR SAFE HANDLING AND USE | | | | |
| Steps to be Taken in Case Material is Released or Spilled | | | | |
| Collect using a HEPA vacuum; do NOT dry sweep (generates dusts). Damp mop residues. Absorb solutions in vermiculite and place in sealed containers. Remove all sources of ignition and ventilate area. Restrict those not involved in cleanup from entering area. Notify appropriate authorities, as required. | | | | |
| Preferred Waste Disposal Method | | | | |
| No citation. | | | | |
| Precautions to be Taken in Handling and Storage | | | | |
| Containers should be protected against physical damage. Store in air-tight containers in a cool, dry, well-ventilated area away from incompatible materials, moisture, and heat. | | | | |
| Other Precautions and Warnings | | | | |
| Personal protective equipment should be used by all persons involved in the storage and handling of lithium bromide. | | | | |
| SECTION VIII - CONTROL MEASURES AND PERSONAL PROTECTIVE EQUIPMENT | | | | |
| Respiratory Protection (<i>specify type</i>) | | | | |
| No exposures levels established. For best protection use a NIOSH-approved respirator with particulate (dust/fume/mist) filters. Otherwise, use a self-contained breathing apparatus in continuous flow mode. | | | | |
| Ventilation | | | | |
| Local exhaust or general mechanical systems recommended. | | | | |
| Protective Gloves | | Eye Protection | | Other Protective Clothing |
| Suitable to protect from skin contact | | Chemical/Dust Goggles | | N/A |
| Work/Hygiene Practices | | | | |
| Always wash hands thoroughly after working with lithium bromide powders and dusts; never bring food, drink, or smoking materials into vicinity of lithium bromide powders or solutions. | | | | |

LITHIUM BROMIDE

LiBr

CAS: 7550-35-8

**IDENTIFICATION AND TYPICAL USES**

Lithium bromide appears as white, cubic, deliquescent crystals or as a white to pink granular powder with no odor and a bitter taste. It is used in pharmaceuticals, in air conditioning, as a humectant, a drying agent, in batteries, as a low-temperature heat-exchange medium, and as a sedative.

RISK ASSESSMENT: HEALTH**General Assessment**

Lithium bromide is toxic through *inhalation*, skin contact (*absorption*), and *ingestion*. The primary systemic effects by all routes of exposure is depression of the central nervous system. There are no reports regarding its carcinogenic, mutagenic, or teratogenic properties in humans or animals.

Inhalation, ingestion, and dermal absorption can cause nausea, vomiting, severe abdominal pain, diarrhea, general weakness, and fatigue. Inhalation can cause respiratory system injury, including bronchitis (inflammation of the bronchial tubes) and/or tracheitis (inflammation of the trachea). Irritation of the nasal cavity and perforation of the nasal septum have also been documented with sneezing, coughing, and shortness of breath (dyspnea). Symptoms of central nervous system depression can include tremors, weight loss, muscular weakness and loss of coordination, slurred speech, and possible seizures and coma.

Lithium bromide can readily pass through intact skin to the bloodstream and cause many of the effects noted above. If dermal absorption should occur in combination with another exposure route (e.g., inhalation), the effects can be serious, even life-threatening.

☠ Acute Health Effects

The following acute (short-term) health effects may occur immediately or shortly after exposure to lithium bromide:

Skin: Irritation and inflammation with possible rash. Absorption is likely to occur.

Eye: Irritation and burning on contact. Injury or damage to vision may occur if not removed immediately.

Lung: Irritation of the nose, throat, and lungs following exposure to lithium bromide dusts. Perforation of the nasal septum, bronchitis, or tracheitis are all possible, especially on high exposure.

CNS: Broad range of serious and possibly life-threatening effects resulting from central nervous system depression up to and including death.

☼ Chronic Health Effects

The following chronic (long-term) health effects may occur at some time after exposure to lithium bromide and can last for months or even years:

Cancer Hazards: According to information presented in the references, lithium has not been shown to cause cancer in test animals. It is not known if long-term exposure to lithium bromide will lead to carcinogenic effects in humans.

Reproductive Hazard: According to information presented in the references, lithium bromide has not been adequately tested for its ability to adversely affect reproduction in test animals.

Other Chronic Effects: Long-term skin exposure to lithium bromide may cause skin eruptions and chronic CNS disturbances (resulting from the bromide) and may cause a disturbances in blood electrolyte balance.

☹ Recommended Risk-Reduction Measures

Personnel should avoid direct contact with lithium bromide. *Engineering controls* are always the most effective method of reducing exposures. The best

protection, especially when working with fine powders and dusts of lithium bromide, is to enclose operations and/or provide explosion-proof, local exhaust ventilation at the site of powder/dust release. While not always operationally feasible, isolating operations can also reduce exposure. Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around lithium bromide. No exposure levels have been established for lithium bromide. However, this does not mean that exposure is without risk. For low or transient exposures, an MSHA/NIOSH-approved respirator equipped with a dust/mist pre-filter may provide adequate protection. Better protection is obtained using a self-contained breathing apparatus (SCBA) with full facepiece operated in pressure demand or a supplied-air respirator. If a full facepiece respirator is not available, then dust goggles or safety glasses with side shields attached should be worn to protect the eyes. To prevent hand and skin exposures, suitable gloves should be used.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with lithium bromide.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where lithium bromide is used or stored.

If symptoms develop or overexposure is suspected, the following tests might be considered:

- Complete blood count.
- Kidney function tests, including urinalysis.
- Nervous system evaluation.

Other methods to reduce exposure include:

- Where possible, enclose operations and use local exhaust ventilation at the site where lithium bromide powder or dust is worked. If local exhaust ventilation or enclosure is not used, respiratory protection should be mandatory.
- Always ensure that proper protective clothing is worn when working with lithium bromide and that personnel are trained in its use and care.
- Wash thoroughly immediately after exposure to lithium bromide and at the end of the work shift or before eating, drinking, or smoking. Clothing

contaminated with lithium bromide dusts or powders should not be taken home where family members can be exposed.

- Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of lithium bromide should be communicated to all exposed and potentially exposed workers.

RISK ASSESSMENT: ENVIRONMENT

General Assessment

The environment is at risk of exposure during transportation, storage, disposal, or destruction of lithium bromide. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of lithium bromide, especially the dusts and powders. Accidental contact with a variety of incompatible materials can result in fire, explosion, and possible contamination of the surrounding environmental mediums (water, soil, and, to a lesser degree, air).

Lithium bromide is considered a non-combustible solid. However, it is incompatible with a number of commonly encountered materials. It will absorb moisture when exposure to air. It will react with ammonia and amines, and will form double salts in contact with other metallic salts (such as copper bromide, mercuric bromide, mercuric iodide, mercuric cyanide). When heated, lithium bromide will dissolve cellulose. These characteristics require special consideration during any emergency situation involving a leak or spill of lithium bromide.

Lithium bromide can enter the environment through spills and industrial waste discharges.

☠ Acute Ecological Effects

Acute (short-term) toxic effects may include the death of animals, birds, or fish and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to lithium bromide.

Insufficient data are available on the short-term effects of lithium bromide exposure to aquatic life, plants, birds, or land animals.

☠* Chronic Ecological Effects

Chronic (long-term) toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed

animals. These effects can be seen long after first exposure(s) to toxic chemicals.

Insufficient data are available on the long-term effects of lithium bromide to aquatic life, plants, birds, or land animals.

💧 *Water Solubility*

Lithium bromide is highly soluble in water. Concentrations of 1000 milligrams and more may mix with a liter of water.

🕒 *Persistence in the Environment*

No information is available in the references on the persistence of lithium bromide in the various environmental mediums.

🐟 *Bioaccumulation in Aquatic Organisms*

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans.

Lithium bromide will not accumulate in fish tissues.

🛡️ *Recommended Risk-Reduction Measures*

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in the contamination of the environment. The correct use of DOT labeling (per the MSDS) on all containers, trucks, and rail cars will enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of lithium bromide should be segregated from incompatible chemicals to minimize the risk of cross-contamination or contact. It should be kept in air-tight containers to avoid moisture absorption. Buildings designated for storage should be properly equipped with appropriate fire protection systems (alarms, signals, sprinklers, emergency lighting, portable extinguishers).

If a spill or leak to the environment has occurred, fire department, emergency response and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those trained in proper spill containment procedures. Contaminated soils should be removed and replaced with clean soil. When environmental contamination oc-

curs, the local and/or state emergency response authorities may require notification. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of lithium bromide. If lithium bromide is spilled or leaked, the following specific steps are recommended:

- ☑ Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened for normal work.
- ☑ Remove all ignition sources.
- ☑ Ventilate area of spill or leak.
- ☑ Collect powdered materials in the safest manner possible and deposit in sealed containers. Do NOT dry sweep (generates airborne dusts). Use a vacuum equipped with a high-efficiency particulate air (HEPA) filter. Absorb solution spills in vermiculite, sand, dry earth, or other absorbent and place in sealed drums for disposal.
- ☑ It may be necessary to dispose of lithium bromide as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving lithium bromide can present a significant threat to business operations. The loss or damage of equipment or facilities due to explosion or fire can significantly affect fiscal viability. Lawsuits that may result from personnel injury/death, public exposures, and/or environmental contamination will also require a serious expenditure of resources.

Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business.

🛡️ *Recommended Risk-Reduction Measures*

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures dealing with safety or emergency response. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

| SECTION V - REACTIVITY DATA | | | | |
|--|--|--|------------------------------|---|
| Stability | | Conditions to Avoid Lithium fluoride is normally stable under routine conditions of storage and handling. Avoid contact with heat and incompatible materials. Do not generate dusty conditions in work or storage areas. | | |
| Stable X | Unstable | Incompatibility (<i>materials to avoid</i>) Incompatible with strong acids (nitric, sulfuric). | | |
| Hazardous Polymerization | | Conditions to Avoid Under normal conditions of temperature and pressure, hazardous polymerization of lithium fluoride is not expected to occur. | | |
| May Occur | Will Not Occur X | Hazardous Decomposition or By-products When heated to decomposition, lithium fluoride can produce toxic and poisonous gases and fumes, including toxic and corrosive hydrogen fluoride. | | |
| SECTION VI - HEALTH HAZARD DATA | | | | |
| Primary Route(s) of Entry: | | Inhalation? X | Absorption (skin)? | Ingestion? |
| Health Hazards INHALATION: Causes severe irritation of the nasal cavity, throat, and respiratory tract. It may cause the mucous membranes to dry and lead to nosebleeds. Excessive exposures can have a cumulative effect and may damage the kidneys. There can also be abdominal pain with diarrhea, nausea, salivation, thirst, sweating, stiff spine and joints, and calcification of the rib and pelvic ligaments. SKIN & EYES: Causes irritation and burns to the eyes and skin similar to that of hydrofluoric acid. The burn can be serious and deep due to the fluoride anion. Dermatitis can occur. INGESTION: Not likely, but possible. Can cause serious gastrointestinal inflammation. | | | | |
| Carcinogenicity Unknown Human Unknown Animal | NTP Listed? No | IARC Cancer Review Group? No | OSHA Regulated? No | Target Organs? Eyes, skin, kidney, CNS, resp. sys., skeletal sys. |
| Medical Conditions Generally Aggravated by Exposure Existing kidney dysfunction may be aggravated by exposure to lithium fluoride. | | | | |
| Emergency and First-aid Procedures Eye contact: Flush immediately with water for 15 minutes (minimum); seek medical attention. Skin contact: Remove all contaminated clothing. Immediately wash area with large amounts of water for 2 to 4 hours or soak in iced Zephiran (0.13%), Epsom salts or a 70% denatured ethyl alcohol solution for 1 to 4 hours. Seek medical assistance. For inhalation: Remove the person from exposure. Provide respiratory assistance and CPR. Transfer to medical facility. If swallowed: Not likely. If accidental ingestion of solutions occurs, seek medical attention or contact poison control center. Do NOT induce vomiting. | | | | |
| SECTION VII - PRECAUTIONS FOR SAFE HANDLING AND USE | | | | |
| Steps to be Taken in Case Material is Released or Spilled Collect using a HEPA vacuum; do NOT dry sweep (generates dusts). Damp mop residues and place in sealed containers. Ventilate area. Restrict those not involved in cleanup from entering area. | | | | |
| Preferred Waste Disposal Method No citation. | | | | |
| Precautions to be Taken in Handling and Storage Containers should be protected against physical damage. Store in tightly containers in a cool, dry, well-ventilated area away from incompatible materials. | | | | |
| Other Precautions and Warnings Personal protective equipment should be used by all persons involved in the storage and handling of lithium fluoride. | | | | |
| SECTION VIII - CONTROL MEASURES AND PERSONAL PROTECTIVE EQUIPMENT | | | | |
| Respiratory Protection (<i>specify type</i>) For best protection use a NIOSH-approved respirator with particulate (dust/fume/mist) filters. Otherwise, use a supplied-air respirator or a self-contained breathing apparatus in continuous flow mode. | | | | |
| Ventilation Local exhaust or general mechanical systems recommended. | | | | |
| Protective Gloves Suitable to protect from skin contact | Eye Protection Chemical/Dust Goggles | Other Protective Clothing Protective Apron or Suit | | |
| Work/Hygiene Practices Always wash hands thoroughly after working with lithium fluoride powders and dusts; never bring food, drink, or smoking materials into vicinity of lithium fluoride powders. | | | | |

LITHIUM FLUORIDE

LiF

CAS: 7789-24-4

**IDENTIFICATION AND TYPICAL USES**

Lithium fluoride appears as a white, fluffy powder of cubic crystals. It is used in welding and soldering flux, in ceramics, as a heat-exchange media, as synthetic crystals in infrared and ultraviolet instruments, as a rocket fuel component, and in radiation dosimetry. It is also a component of fuels used for molten salt reactors and in X-ray diffraction.

RISK ASSESSMENT: HEALTH***General Assessment***

Lithium fluoride is primarily toxic through *inhalation*, and skin contact (although dermal absorption leading to toxic systemic effects has not been reported). Ingestion is unlikely but possible. The primary systemic effects appear to result from the fluoride content. There are no reports regarding its carcinogenic, mutagenic, or teratogenic properties in humans or animals.

Inhalation of low concentrations does not appear to cause any acute toxic effects. This is thought to be due to its low water solubility. However, it can be a cumulative poison. This is especially true for individuals with low sodium intake. Excessive lithium exposure can damage the kidneys and lead to central nervous system depression. Exposure to fluorides cause irritation to the eyes, nose, throat, and mucosa of the respiratory tract. There can be nasal cavity dryness and nosebleeds. Systemic effects include nausea, severe abdominal pain with vomiting and diarrhea, excessive salivation and extreme thirst, sweating, stiffening of the spine and joints with eventual calcification of the rib and pelvic ligaments.

Skin contact results in immediate irritation and burning rash. Contact with diluted solutions as low as 20% lithium fluoride may not burn immediately. However, if not completely removed, the fluoride anion's affinity for calcium can cause deep and painful burns. Dermatitis may also develop. Eye contact can cause irritation, burns, and possible damage to vision.

☠ *Acute Health Effects*

The following acute (short-term) health effects may occur immediately or shortly after exposure to lithium fluoride:

- Skin:** Irritation and inflammation with possible deep burns and rash.
- Eye:** Irritation and burning on contact. Injury or damage to vision may occur if not removed immediately.
- Lung:** Irritation of the nose, throat, and lungs following exposure to lithium fluoride dusts. Dryness and nosebleeds have occurred.
- CNS:** Broad range of possible effects resulting from the lithium content.

☘ *Chronic Health Effects*

The following chronic (long-term) health effects may occur at some time after exposure to lithium fluoride and can last for months or even years:

Cancer Hazards: According to information presented in the references, lithium has not been shown to cause cancer in test animals. It is not known if long-term exposure to lithium fluoride will lead to carcinogenic effects in humans.

Reproductive Hazard: According to information presented in the references, lithium fluoride has not been adequately tested for its ability to adversely affect reproduction in test animals.

Other Chronic Effects: Prolonged exposures to fluorides can lead to fluorosis which causes changes in the bones and ligaments, and possible kidney damage.

🛡 *Recommended Risk-Reduction Measures*

Personnel should avoid direct contact with lithium fluoride. *Engineering controls* are always the most effective method of reducing exposures. The best

Risk Management for Hazardous Chemicals

protection, especially when working with fine powders and dusts of lithium fluoride, is to enclose operations and/or provide explosion-proof, local exhaust ventilation at the site of powder/dust release. While not always operationally feasible, isolating operations can also reduce exposure. Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around lithium fluoride. For exposures over the PEL (2.5 mg/m³ for fluorides), a chemical cartridge respirator equipped with a dust/mist pre-filter may provide adequate protection. For better protection, use of a self-contained breathing apparatus (SCBA) with full facepiece operated in pressure demand or a supplied-air respirator is recommended. If a full facepiece respirator is not available, then dust goggles or safety glasses with side shields attached should be worn to protect the eyes. To prevent hand and skin exposures, suitable gloves should be used. Glove manufacturers should be contacted and permeation studies obtained before final glove selections are made.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with lithium fluoride.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where lithium fluoride is used or stored.

Before beginning employment and at regular intervals thereafter (e.g., semi-annual), the following medical testing is recommended:

- Urinalysis.
- Musculoskeletal examination.
- Lung function tests.
- Kidney function tests.

If symptoms develop or overexposure is suspected, the following tests might be considered:

- Nervous system evaluation.

Other methods to reduce exposure include:

- Where possible, enclose operations and use local exhaust ventilation at the site where lithium fluoride powder or dust is worked. If local exhaust ventilation or enclosure is not used, respiratory protection should be mandatory.

- Always ensure that proper protective clothing is worn when working with lithium fluoride and that personnel are trained in its use and care.
- Wash thoroughly immediately after exposure to lithium fluoride and at the end of the work shift or before eating, drinking, or smoking. Clothing contaminated with lithium fluoride dusts or powders should not be taken home where family members can be exposed.
- Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of lithium fluoride should be communicated to all exposed and potentially exposed workers.

RISK ASSESSMENT: ENVIRONMENT***General Assessment***

The environment is at risk of exposure during transportation, storage, disposal, or destruction of lithium fluoride. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of lithium fluoride, especially the dusts and powders. Accidental contact with a variety of incompatible materials can result in fire, explosion, and possible contamination of the surrounding environmental mediums (water, soil, and, to a lesser degree, air).

Lithium fluoride is considered a non-combustible solid. However, it is incompatible with a number of commonly encountered acids. Contact with acids, especially when heated, can produce highly toxic and corrosive hydrogen fluoride gas. Improper handling during use, transportation, storage, or disposal can result in injury to personnel and/or damage to the environment. These characteristics require special consideration during any emergency situation involving a leak or spill of lithium fluoride. Lithium fluoride can enter the environment through spills and industrial discharges.

☠ Acute Ecological Effects

Acute (short-term) toxic effects may include the death of animals, birds, or fish and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to lithium fluoride.

Insufficient data are available on the short-term effects of lithium fluoride exposure to aquatic life, plants, birds, or land animals.

☪ Chronic Ecological Effects

Risk Management for Hazardous Chemicals

Chronic (long-term) toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals.

Insufficient data are available on the long-term effects of lithium fluoride to aquatic life, plants, birds, or land animals.

◆ *Water Solubility*

Lithium fluoride is slightly soluble in water. Concentrations of 1 to 100 milligrams will mix with a liter of water.

⌚ *Persistence in the Environment*

No information is available in the references on the persistence of lithium fluoride in the various environmental mediums. However, hydrogen fluoride is slightly persistent in the aquatic environment, with a half-life of less than 2 and 20 days. The half-life of a pollutant is the amount of time it takes for one half of the chemical to be degraded.

🌊 *Bioaccumulation in Aquatic Organisms*

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans.

Lithium fluoride will not accumulate in fish tissues.

🚫 *Recommended Risk-Reduction Measures*

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in the contamination of the environment. The correct use of labeling on all containers, trucks, and rail cars will enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of lithium fluoride should be segregated from incompatible chemicals to minimize the risk of cross-contamination or contact. It should be kept in tightly-closed in a cool, dry location. Buildings designated for storage should be properly equipped with appropriate fire protection systems (alarms, signals, sprinklers, emergency lighting, portable extinguishers).

If a spill or leak to the environment has occurred, fire department, emergency response and/or hazardous

materials spill personnel should be notified immediately. Cleanup should be attempted only by those trained in proper spill containment procedures. Contaminated soils should be removed and replaced with clean soil. When environmental contamination occurs, the local and/or state emergency response authorities may require notification. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of lithium fluoride. If lithium fluoride is spilled or leaked, the following specific steps are recommended:

- ☑ Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened for normal work.
- ☑ Ventilate area of spill or leak.
- ☑ Collect powdered materials in the safest manner possible and deposit in sealed containers. Do NOT dry sweep (generates airborne dusts). Use a vacuum equipped with a high-efficiency particulate air (HEPA) filter. Damp mop residues and collect for disposal. A water spray can be effective in controlling dust clouds and protecting response workers. Be aware of runoff. Collect for disposal.
- ☑ Absorb solution spills in vermiculite, sand, dry earth, or other absorbent and place in sealed drums for disposal. Avoid skin contact during cleanup operations.
- ☑ It may be necessary to dispose of lithium fluoride as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving lithium fluoride can present a significant threat to business operations. The loss or damage of equipment or facilities due to explosion or fire can significantly affect fiscal viability. Lawsuits that may result from personnel injury/death, public exposures, and/or environmental contamination will also require a serious expenditure of resources. Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business.

Recommended Risk-Reduction Measures

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures dealing with safety or emergency response. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

Decomposes in water rapidly to form lithium hydroxide and hydrogen. Soluble in ether and slightly soluble in acid. Insoluble in benzene and toluene.

Appearance and Odor

Odorless, off-white or light blue-gray, translucent, crystalline solid or white powder.

SECTION IV - FIRE AND EXPLOSION HAZARD DATA

| | |
|--|--|
| Flash Point (method used) Not Determined | Explosive Limits in Air % by Volume LEL: Not Determined UEL: Not Determined |
| NFPA Classification Combustible Solid | Autoignition Temperature 392°F (200°C) |

Extinguishing Media

Use special mixture of dry chemicals (Lith-X® powder, G-1 graphite powder) or smother with sand.

Special Fire Fighting Procedures

Poisonous gases are produced in fire; wear full protective clothing and self-contained breathing apparatus (SCBA). Isolate area and deny entry to those not involved in response procedures. May give off toxic fumes of unburned material. Move containers from fire area if it can be done without risk. Do NOT use water, carbon dioxide, or halogenated agents to fight fire.

Unusual Fire and Explosion Hazards

Reacts rapidly with water to form flammable hydrogen gas. Lithium hydride ignites spontaneously in air and may re-ignite after fire has been extinguished.

SECTION V - REACTIVITY DATA

| | | |
|---------------------------------|----------------------------|---|
| Stability | | Conditions to Avoid Thermally unstable, darkens on exposure to light, and can ignite spontaneously on exposure to air or heat. Avoid contact with incompatible materials. |
| Stable | Unstable X | Incompatibility (<i>materials to avoid</i>) Strong oxidizers (chlorine), water, halogenated compounds, nitrous oxide, lower alcohols, carboxylic acids, ammonia, dinitrogen oxide, oxygen, moisture, and wet combustible materials. |
| Hazardous Polymerization | | Conditions to Avoid Under normal conditions of temperature and pressure, hazardous polymerization of lithium hydride is not expected to occur. |
| May Occur | Will Not Occur X | Hazardous Decomposition or By-products When heated to decomposition, lithium hydride emits toxic and irritating alkali fumes and explosive hydrogen gas. |

SECTION VI - HEALTH HAZARD DATA

| | | | |
|-----------------------------------|-------------------------|--------------------|------------------------|
| Primary Route(s) of Entry: | Inhalation? X | Absorption (skin)? | Ingestion? X |
|-----------------------------------|-------------------------|--------------------|------------------------|

Health Hazards

INHALATION: Causes irritation of the eyes, nose, throat, and respiratory system with coughing, sneezing, dyspnea, mucous membrane irritation in the nasal cavity leading to ulceration of the septum, chemical bronchitis, or delayed pulmonary edema. Nervous system effects also possible, including mental confusion, nausea, muscular twitching, and blurred vision.

SKIN & EYES: Skin contact causes serious caustic burns, itchy rash, and surface inflammation. Eye contact may cause burns, irritation, corneal scarring, and perhaps permanent damage.

INGESTION: Burning of the mouth, esophagus, and digestive tract. Pain in the chest, stomach, and painful swallowing.

| | | | | |
|---|-------------|---------------------------|--|---|
| Carcinogenicity | NTP Listed? | IARC Cancer Review Group? | OSHA Regulated? | Target Organs? |
| Unknown Human Unknown Animal | No | No | 29 CFR 1910.1000 Table Z-1 (skin) | CNS, skin, eyes, respiratory system. |

Medical Conditions Generally Aggravated by Exposure

Existing chronic respiratory diseases may be aggravated by exposure.

Emergency and First-aid Procedures

Eye contact: Flush immediately with water for 15 minutes (minimum); seek medical attention. **Skin contact:** Remove all contaminated clothing. Wash area with large amounts of soap and water. Seek medical assistance. For **inhalation:** Remove the person from exposure. Provide respiratory assistance and CPR. Transfer to medical facility. Observe for 48 hours for lung effects. If **swallowed:** Contact poison control center. Unless told otherwise, give 1-2 glasses of water to dilute. Do NOT induce vomiting. Never attempt to give an unconscious or convulsing person anything by mouth.

SECTION VII - PRECAUTIONS FOR SAFE HANDLING AND USE

Steps to be Taken in Case Material is Released or Spilled

Collect powdered material using a vacuum equipped with HEPA filter and deposit in sealed drums for disposal. Avoid skin contact. Do NOT dry sweep (generates dusts). Keep water away. Ventilate area. Restrict those not involved in cleanup from entering area.

Preferred Waste Disposal Method

No citation.

Precautions to be Taken in Handling and Storage

Do not store lithium hydride in the presence of incompatible chemicals or materials. Store in tightly closed containers in a cool, dark, well-ventilated area. Personnel working with lithium hydride should be trained on its proper handling and storage prior to being assigned to such responsibilities.

Other Precautions and Warnings

Keep away from water and halogenated compounds. Bulk storage of lithium hydride is not recommended. Keep stored under inert atmosphere, if possible.

SECTION VIII - CONTROL MEASURES AND PERSONAL PROTECTIVE EQUIPMENT

Respiratory Protection (*specify type*)

PEL is extremely low (0.025 ppm). Use a self-contained breathing apparatus (SCBA) with full facepiece or a supplied-air respirator operated in pressure demand or other positive pressure mode.

Ventilation

Local exhaust or general mechanical systems recommended.

| | | |
|---|---|--|

|---|---|--|

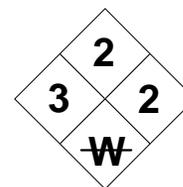

Work/Hygiene Practices

Always wash hands thoroughly after using chemical; never bring food, drink, or smoking materials into vicinity of chemicals.

LITHIUM HYDRIDE

LiH

CAS: 7580-67-8

**IDENTIFICATION AND TYPICAL USES**

Lithium hydride appears as an odorless, off-white or light blue-gray, translucent, crystalline solid or white powder. It is used as a desiccant, as a source of hydrogen, as a condensing agent in organic synthesis, in the preparation of lithium amide and double hydrides, in nuclear shielding material, and as a reducing agent.

RISK ASSESSMENT: HEALTH***General Assessment***

Lithium hydride is a human poison primarily by *inhalation*, causing toxic systemic effects targeting the respiratory system. This is due to the formation of highly caustic lithium hydroxide when lithium hydride contacts moisture. Therefore, the eyes, mucous membranes, and lungs are particularly at risk. Its carcinogenicity, teratogenicity, and mutagenicity are currently unknown in humans.

Inhalation of lithium hydride dusts can be irritating to the nose, throat, mucosa, and the upper respiratory tract. Symptoms can include coughing, sneezing, dyspnea, ulceration of the nasal septa, chemical bronchitis, and the possibility of pulmonary edema (a dangerous buildup of fluid in the lungs). Pulmonary edema can be delayed up to 48 hours or more, thereby creating a false sense of security with regard to health exposure risk. There can also be effects subsequent to lithium's ability to depress the central nervous system. These effects can include headache, nausea, dizziness, drowsiness, lightheadedness, muscular twitching, tremors, mental confusion, blurred vision, coma, and, in severe cases, death.

Ingestion of lithium hydride can cause burning of the mouth, esophagus, and gastrointestinal tract with deep, burning pain in the chest and stomach and pain on swallowing.

Skin contact causes painful caustic burns, especially if the contact area is moist (sweat). Even at relatively low concentrations (0.2 to 0.5 mg/m³) the skin may become itchy and inflamed. Eye contact can

result in serious burns, corneal scarring, and possible damage to loss or even loss of vision.

☠ *Acute Health Effects*

The following acute (short-term) health effects may occur immediately or shortly after exposure to lithium hydride:

Skin: Irritation and possible rash. Moisture on skin's surface forms lithium hydroxide which will cause serious caustic burns.

Eye: Severe burns, corneal scarring, and possible damage to vision.

Lung: Severe irritation of the nose, throat, and esophagus. Possible pulmonary edema.

CNS: Dizziness, headaches, nausea, vomiting, muscle spasms, tremor, fatigue, convulsions, dyspnea, nervousness, drowsiness, loss of coordination, coma, and even death.

☘ *Chronic Health Effects*

The following chronic (long-term) health effects may occur at some time after exposure to lithium hydride and can last for months or even years:

Cancer Hazards: According to the information presented in the references, lithium hydride has not been adequately tested for its ability to cause cancer in test animals.

Reproductive Hazard: According to the information presented in the references, lithium hydride has not been adequately tested for its ability to adversely affect reproduction. However, lithium has been shown to cross the placenta barrier.

Other Chronic Effects: Prolonged contact with low-level concentration of lithium hydride can lead to the development of emphysema.

🛡 *Recommended Risk-Reduction Measures*

Personnel should avoid direct contact with lithium hydride. It is a toxic, human poison on inhalation. If

a less toxic chemical cannot be substituted for a hazardous substance, *engineering controls* are the most effective method of reducing exposures. The best protection is to enclose operations and/or provide local exhaust ventilation at the site of chemical release. While not always operationally feasible, isolating operations can also reduce exposure.

Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around lithium hydride. This chemical has an extremely low permissible exposure limit (0.025 ppm) that is difficult to accurately monitor. Therefore, prudent risk management requires a conservative approach to personal protection. While a chemical respirator with a dust/mist pre-filter may suffice, the best protection is obtained using a supplied-air respirator operated in continuous flow mode or a self-contained breathing apparatus (SCBA) with full facepiece operated in pressure demand or positive pressure mode. If a full facepiece is not available, then chemical/dust goggles should be worn to protect the eyes. Whenever lithium hydride is being mixed with liquids, a chemical splash hazard exists and a face shield and rubber apron should be worn. To prevent hand and skin exposures, protective gloves should be used. Glove manufacturers should be contacted and permeation studies obtained *before* final glove selections have been made.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with lithium hydride.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where lithium hydride is used or stored.

If symptoms develop or overexposure is suspected, the following medical tests may be useful:

- Lung function tests.
- Kidney function tests.
- Consider chest X-ray after an acute overexposure to lithium hydride (may be negative if taken immediately following exposure due to delayed development of pulmonary edema).

Any evaluation should include a careful medical history of past and present symptoms with an examination. However, medical tests that evaluate existing

damage are not a substitute for controlling exposure. Also, since smoking can cause heart disease, emphysema, lung cancer, and other respiratory diseases, smokers may experience symptoms more rapidly than non-smokers under the same conditions of exposure. Prudent risk management requires proper consideration of *all* possible factors that may be causing the appearance of exposure symptoms in the workplace.

Other methods to reduce exposure include:

- Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not used, respiratory protection should be mandatory.
- Always ensure that proper protective clothing is worn when using chemical substances.
- Wash thoroughly immediately after exposure to lithium hydride and at the end of the work shift or before eating, drinking, or smoking.
- Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of lithium hydride should be communicated to all exposed or potentially exposed workers.
- Eye wash stations should be provided in work areas. If the potential for whole body exposure exists, then safety showers should also be provided.

RISK ASSESSMENT: ENVIRONMENT

General Assessment

The environment is at risk of exposure during transportation, storage, disposal, or destruction of lithium hydride. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance. Accidental spills, large or small, can result in fire, explosion, and possible contamination of the surrounding environmental mediums (water, soil, and air).

Lithium hydride is considered a combustible solid. It can ignite spontaneously in air or on exposure to heat. In reaction to halogenated compounds, it yields products that may explode on impact (hydrogen gas). If it should contact water or moisture, it will produce extremely caustic lithium hydroxide as well as flammable and explosive hydrogen gas. These characteristics require special consideration during any emergency situation involving a leak or spill of lithium hy-

hydride or lithium hydride mixtures. Should lithium hydride ever come into contact with other incompatible substances, such as strong oxidizers or acids, either during use, transportation, or storage, violent reactions can occur.

Lithium hydride can enter the environment through industrial discharges and from spills.

☠ *Acute Ecological Effects*

Acute (short-term) toxic effects may include the death of animals, birds, or fish and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to lithium hydride.

Insufficient data are available to evaluate or predict the short-term effects of lithium hydride to aquatic life, plants, birds, or land animals.

🕒 *Chronic Ecological Effects*

Chronic toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals.

Insufficient data are available to evaluate or predict the long-term effects of lithium hydride to aquatic life, plants, birds, or land animals.

💧 *Water Solubility*

Lithium hydride is not soluble in water. It reacts and decomposes to form lithium hydroxide and free hydrogen gas, which is explosive.

🕒 *Persistence in the Environment*

Lithium hydride is non-persistent in water, with a half-life of less than 2 days. The half-life of a pollutant is the amount of time it takes for one half of the chemical to be degraded.

🐟 *Bioaccumulation in Aquatic Organisms*

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans.

Lithium is not expected to accumulate in the edible tissues of fish normally consumed by humans.

🛡️ *Recommended Risk-Reduction Measures*

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in a leak or spill to the environment. The correct use of DOT labeling (per the MSDS) on all containers, trucks, and rail cars will enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of lithium hydride should be segregated from incompatible chemicals to minimize the risk of cross-contamination or contact. A nitrogen purge is recommended inside all storage vessels and bulk storage containers, if possible. Precautions must be taken to ensure all contact with water or moisture is prevented in use or storage.

If a spill or leak to the environment has occurred, fire department, emergency response and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those trained in proper spill containment procedures. Contaminated soils should be removed for incineration and replaced with clean soil. If lithium hydride should contact the water table, aquifer, or navigable waterway, remediation activities should be prompt. When such spills occur, the local and/or state emergency response authorities must be notified. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of lithium hydride. If lithium hydride is spilled or leaked, the following specific steps are recommended:

- ☑ Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened to normal work.
- ☑ Collect powdered material in the most convenient (safe) manner possible and deposit in sealed containers. Do NOT dry sweep (generates airborne dusts). Use a vacuum equipped with a HEPA filter instead. If liquid solutions are spilled, use vermiculite to absorb and place in a sealed drum.
- ☑ It may be necessary to dispose of lithium hydride as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving lithium hydride can present a significant threat to business operations. The loss or damage of equipment or facilities can significantly affect fiscal viability. Lawsuits that may result from personnel injury/death, public exposures, and/or environmental contamination will also require a serious expenditure of resources. Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business.

🕒 Recommended Risk-Reduction Measures

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures dealing with safety or emergency response. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

MAGNESITEMgCO₃

CAS: 546-93-0

**IDENTIFICATION AND TYPICAL USES**

Magnesite appears as a white, friable mass or a crystalline, bulky powder with no odor. It is mined as a natural material. The synthetic variety is known as magnesium carbonate. It occurs in North America in California, Washington, and Nevada, as well as in Austria and Greece. It is used to make various grades of magnesium oxide and in the production of carbon dioxide. The synthetic variety is used in foods as a drying, color retention, and anti-caking agent. It is also used in the manufacture of magnesium citrate, in certain inks, in the making of glass, pharmaceuticals, dentifrice, cosmetics, and in heat insulation.

RISK ASSESSMENT: HEALTH***General Assessment***

Magnesite exhibits relatively low toxicity in humans by *inhalation* and *ingestion*. It is generally considered a nuisance particulate. However, exposure to sufficient quantities can pose a serious health risk. There is no information on its carcinogenic, mutagenic, or teratogenic capabilities.

Inhalation causes irritation to the eyes, nose, throat, and mucosa of the upper respiratory tract with cough and congestion. If ingested, magnesium salts will be slowly absorbed. However, large amounts can cause systemic poisoning with symptoms of diarrhea, kidney effects, and depression of the central nervous system (CNS). This can lead to failed reflexes with progression to respiratory failure or cardiac arrest and death.

Acute Health Effects

The following acute (short-term) health effects may occur immediately or shortly after human exposure to magnesite:

Skin: May cause mild irritation, depending on the conditions and length of exposure.

Eye: Mild to moderate irritation.

Lung: Irritation of the mucosa of the eyes, nose, throat, and respiratory tract.

Other: Ingestion of excessive quantities of magnesite can cause gastrointestinal effects, kidney problems, and depression of the central nervous system that can lead to death.

Chronic Health Effects

The following chronic (long-term) health effects may occur at some time after exposure to magnesite and can last for months or even years:

Cancer Hazards: According to the references, magnesite has not been shown to cause cancer in animals.

Reproductive Hazard: According to the references, there are no reports of any teratogenic or reproductive effects resulting from exposure to magnesite.

Other Chronic Effects: None reported.

Recommended Risk-Reduction Measures

Even though the toxicity of magnesite is considered to be relatively low, personnel should avoid direct contact with magnesite. If a less toxic material or compound cannot be substituted for magnesite, then *engineering controls* are the most effective method of reducing exposures. The best protection is to enclose operations and/or provide local exhaust ventilation at the site of magnesite dust release. While not always operationally feasible, isolating operations can also reduce exposure. Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around magnesite. A supplied-air respirator operated in continuous flow mode or a self-contained breathing apparatus (SCBA) with full facepiece operated in pressure demand is recommended for the greatest possible respiratory protection. However, for low or infrequent exposure, an MSHA/NIOSH-approved full facepiece

respirator with a high efficiency particulate air (HEPA) filter may be used. If a full facepiece is not available, then chemical/dust goggles should be worn to protect the eyes. A face shield and protective apron should also be worn. To prevent hand and skin exposures, gloves should be used.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with magnesite.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where magnesite is used or stored.

Before beginning employment working with magnesite, and at regular intervals thereafter (e.g., annually), those personnel with frequent or potentially high exposures should be provided the following recommended medical tests:

- Kidney function tests (establish baseline).

If symptoms develop or overexposure is suspected, consider the following additional tests:

- Kidney function tests (compare to baseline).
- Neurological examination.
- Lung function tests.

Any evaluation should include a careful history of past and present symptoms with an examination. Medical tests that simply look for existing damage are not a substitute for controlling exposures. Also, since smoking can cause heart disease as well as lung cancer, emphysema, and other known respiratory problems, smokers exposure to magnesite may experience symptoms more rapidly than non-smokers under the same conditions of exposure. Prudent risk management requires careful consideration of *all* factors which may be causing exposure symptoms in the workplace.

Other methods to reduce exposure include:

- Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not used, respiratory protection should be mandatory.
- Always ensure that proper protective clothing is worn when using chemical substances. Proper maintenance and care of protective equipment is essential to its proper function.

- Wash thoroughly immediately after exposure to magnesite and at the end of the work shift or before eating, drinking, or smoking.
- Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of magnesite should be communicated to all exposed and potentially exposed workers.
- Eye wash stations should be provided in the immediate work area for emergency use. If there is a possibility of skin exposure to magnesite, emergency shower facilities should be provided.
- Workers whose clothing has been contaminated by magnesite should change into clean clothes before leaving work. Contaminated work clothing should be laundered only by individuals who have been informed of the hazards of exposure to magnesite.

RISK ASSESSMENT: ENVIRONMENT

General Assessment

As a naturally occurring mineral, magnesite poses very little threat to the environment. However, accidental spills or releases to the environment can occur during transportation, storage, disposal, or destruction of magnesite. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance. Accidental spills, large or small, where magnesite contacts incompatible commodities can result in release of toxic products (depending upon conditions of spill), and possible contamination of the surrounding environmental mediums (water, soil, and air).

Magnesite is considered a non-combustible solid. However, finely divided dusts and powders may create an explosive mixture in air in closed spaces. It is incompatible with many acids and formaldehyde, and extreme caution is required in handling, storage, transportation, and disposal of magnesite. These characteristics also require special consideration during any emergency situation involving a leak or spill of magnesite powder or dust. Should magnesite ever come into contact with incompatible substances either during use, transportation, storage, or disposal, violent and even explosive reactions are possible.

Magnesite may enter the environment as a result of industrial and municipal waste treatment plant discharges and from spills.

☠ *Acute Ecological Effects*

Acute (short-term) toxic effects may include the death of animals, birds, or fish and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to magnesite. Magnesium and its salts have slight acute toxicity to aquatic life. Insufficient data are available to evaluate the short-term effects of magnesite to plants, birds, or land animals.

🌱 *Chronic Ecological Effects*

Chronic (long-term) toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals. Magnesium and its salts have slight chronic toxicity to aquatic life. Insufficient data are available to evaluate or predict the long-term effects of magnesite to plants, birds, or land animals.

💧 *Water Solubility*

Magnesite is nearly insoluble (0.01%) in water. Concentrations of less than 1 milligram may mix with a liter of water.

🕒 *Persistence in the Environment*

Magnesite is highly persistent in water, with a half-life greater than 200 days. The half-life of a pollutant is the amount of time it takes for one half of the chemical to be degraded. Magnesite is also naturally present in soils, with its three hydrates (barrington, nesquehonite, and landsforite).

🐟 *Bioaccumulation in Aquatic Organisms*

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans.

The concentration of magnesite found in fish tissues is expected to be about the same as the average concentration of magnesite in the water from which the fish was taken.

🛡️ *Recommended Risk-Reduction Measures*

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in a leak or

spill of magnesite dusts or powders into the environment. The correct use of labeling on all containers, trucks, and rail cars will enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of magnesite should be segregated from incompatible chemicals to minimize the risk of cross-contamination or contact. Care should be taken to prevent physical damage to storage containers. Also, dusty conditions must be avoided in storage and use areas. When magnesite comes into contact with acids, it will readily liberate excessive amounts of carbon dioxide which is not only toxic, it can also cause a dangerous pressure buildup inside closed containers and may lead to an explosion.

If a spill or leak to the environment has occurred, fire department, emergency response and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those trained in proper spill containment procedures. Contaminated soils should be removed for decontamination and replaced with clean soil. If magnesite should contact the water table, aquifer, or navigable waterway, time is of the essence. It is slightly soluble and total remediation may not be possible. The local and/or state emergency response authorities may require notification. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of magnesite.

If magnesite is spilled or leaked, the following specific steps are recommended:

- Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened for normal work.
- Remove all ignition sources from area.
- Ventilate area of spill or leak.
- Collect powdered materials in the safest manner possible and deposit in sealed containers. Recommend using a vacuum equipped with a high-efficiency particulate air (HEPA) filter. Do not dry sweep (generates airborne dusts). Damp mop residues and collect for disposal. Water spray can be used to knock down vapors. Runoff should also be collected for disposal.
- It may be necessary to dispose of magnesite as a hazardous waste. The responsible state agency or the regional office of the federal Environ-

mental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving magnesite can present a significant threat to business operations. The loss or damage of equipment or facilities can significantly affect fiscal viability. Lawsuits that may result from personnel injury/death, public exposures, and/or environmental contamination will also require a serious expenditure of resources. Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business.

Recommended Risk-Reduction Measures

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures for responding to chemical incidents. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

| Primary Route(s) of Entry: | | Inhalation? X | Absorption (skin/eye)? | Ingestion? X |
| Health Hazards INHALATION: The dusts can produce irritation of the eyes and mucous membranes. It may react with the water content in the bronchial passages to form caustic magnesium hydroxide which can damage the lungs. Inhalation of the fumes can cause metal fume fever with symptoms of cough, a feeling of chest pressure, leukocytosis, and other febrile (feverish) conditions. EYES & SKIN: Causes skin sores that resist healing and accumulate gas under the skin (small blisters). The powder metal ignites easily on moist skin and eyes causing serious burns. INGESTION: Large doses can cause gastrointestinal irritation and other unspecified effects. | | | | |
| Carcinogenicity Unknown Human Unknown Animal | NTP Listed? No | IARC Cancer Review Group? No | OSHA Regulated? No | Target Organs? Respiratory system, eyes, skin, CNS, kidneys. |
| Medical Conditions Generally Aggravated by Exposure Existing kidney dysfunction may be aggravated by ingestion of magnesium salts. | | | | |
| Emergency and First-aid Procedures Eye contact: Do not allow victim to keep eyes tightly shut. Flush immediately with water for 15 minutes (minimum); seek medical attention. Skin contact: Remove all contaminated clothing. Immediately wash area with flooding amounts of water. For reddened or blistered skin, seek medical assistance. For inhalation: Remove the person from exposure. Provide respiratory assistance and CPR. Transfer to medical facility. If swallowed: Seek medical attention. Rinse mouth with water. Give 1 to 2 glasses of water. Do NOT induce vomiting. Never give anything by mouth to an unconscious or convulsing person. | | | | |
| SECTION VII - PRECAUTIONS FOR SAFE HANDLING AND USE | | | | |
| Steps to be Taken in Case Material is Released or Spilled Collect powdered materials in most convenient and safe manner and deposit in clean, dry, sealed, metal containers. Dry sweep not recommended. Use HEPA vacuum. Ventilate area of spill. Restrict those not involved in cleanup from entering area. Do NOT use water. | | | | |
| Preferred Waste Disposal Method Reclaim scrap. | | | | |
| Precautions to be Taken in Handling and Storage Store to avoid contact with incompatible materials. Prevent physical damage to containers. Keep containers tightly closed. Keep moisture and sources of heat away. Use non-sparking tools. | | | | |
| Other Precautions and Warnings Avoid excessive dust generation in storage and handling areas. Personnel should be trained on the proper precautions for working with magnesium compounds <i>before</i> initial assignment. | | | | |
| SECTION VIII - CONTROL MEASURES AND PERSONAL PROTECTIVE EQUIPMENT | | | | |
| Respiratory Protection (<i>specify type</i>) For dust exposures, use a respirator with a HEPA filter; otherwise, use a supplied-air respirator or a self-contained breathing apparatus with full facepiece operated in positive pressure mode. | | | | |
| Ventilation Local exhaust (preferred) at site of chemical work or general ventilation. | | | | |
| Protective Gloves Impervious Material | | Eye Protection Chemical/Dust Goggles or Face Mask | | Other Protective Clothing Protective Apron, Boots |
| Work/Hygiene Practices Always wash hands thoroughly after using chemical; never bring food, drink, or smoking materials into vicinity of chemicals. | | | | |

MAGNESIUM

Mg

CAS: 7439-95-4

IDENTIFICATION AND TYPICAL USES

Magnesium appears as a silvery-white, moderately hard, alkaline earth metal. It is metallic element of atomic number 12, group IIA of the periodic table, atomic weight 24.305, and valance of 2 with 3 isotopes. It is used in aluminum alloys for structural parts, in diecast auto parts, in missiles, space vehicles, in powder for pyrotechnics and flares, and in flash photography. It is also used in the production of iron, nickel, zinc, titanium, zirconium, in antiknock gasoline additives, in making magnesium compounds and Gringard syntheses, in cathodic protection, as a reducing agent, in desulfurizing iron in steel manufacturing, in precision instruments, in optical mirrors, and in dry and wet batteries.

RISK ASSESSMENT: HEALTH

General Assessment

The toxicity of magnesium metal in humans is not easily characterized. It can enter the body and cause varying degrees of adverse health effects through *inhalation* and *ingestion*. There is no information on its carcinogenic, mutagenic, or teratogenic capabilities.

Inhalation of the dusts and particles of magnesium can irritate the eyes and nasal passages. Magnesium may react with the water content in the bronchial passages to form caustic magnesium hydroxide which can cause severe burns and tissue damage. Magnesium fumes in the oxide form can also irritate the eyes, nose, throat, and respiratory tract and may cause metal fume fever with cough, tightness and pressure in the chest, nausea, vomiting, and other febrile (feverish) symptoms. Leukocytosis (increase of leukocytes in the blood) may also develop.

Magnesium particles that become imbedded in the skin can cause the development of slow healing sores and gaseous blebs (small blisters). If the skin is moist, burns may be serious and destructive.

☠ Acute Health Effects

The following acute (short-term) health effects may occur immediately or shortly after human exposure to magnesium:

Skin: May cause serious irritation and even burns, especially if the skin is moist. Small blisters can develop that will heal slowly and may become infected.

Eye: Severe irritation and possible burns due to the eyes' moisture content. Damage can be serious and permanent.

Lung: Irritation of the mucosa of the eyes, nose, throat, and respiratory tract.

CNS: Breathing heated fumes can cause metal fume fever with specific action on the central nervous system.

☼ Chronic Health Effects

The following chronic (long-term) health effects may occur at some time after exposure to magnesium and can last for months or even years:

Cancer Hazards: According to the references, magnesium has not been shown to cause cancer in animals.

Reproductive Hazard: According to the references, there are no reports of any teratogenic or adverse reproductive effects resulting from exposure to magnesium.

Other Chronic Effects: None reported.

🛡 Recommended Risk-Reduction Measures

The specific human toxicity of magnesium is not easily characterized and, therefore, personnel should avoid direct contact with magnesium. If a less toxic material or compound cannot be substituted for magnesium, then *engineering controls* are the most effective method of reducing exposures. The best protection is to enclose operations and/or provide local exhaust ventilation at the site of magnesium dust release.

While not always operationally feasible, isolating operations can also reduce exposure. Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around magnesium. No exposure limits have been established specifically for magnesium metal. This does not mean that exposure is without a health risk. Other magnesium compounds have levels set relatively low (10 mg/m^3 for magnesium oxide, for example). For low or transient exposures, a chemical cartridge respirator equipped with a high-efficiency particulate air (HEPA) filter and a dust/mist pre-filter may provide adequate respiratory protection. Better protection is obtained using a supplied-air respirator operated in continuous flow mode or a self-contained breathing apparatus (SCBA) with full facepiece operated in pressure demand. If a full facepiece is not available, then chemical/dust goggles should be worn to protect the eyes. A face shield and protective apron should also be worn. To prevent hand and skin exposures, gloves should be used. Glove manufacturers should be contacted *before* selections are made.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with magnesium.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where magnesium is used or stored.

Before beginning employment working with magnesium, and at regular intervals thereafter (e.g., annually), those personnel with frequent or potentially high exposures should be provided the following recommended medical tests:

- Kidney function tests (establish baseline).

If symptoms develop or overexposure is suspected, consider the following additional tests:

- Kidney function tests (compare to baseline).
- Neurological examination.
- Lung function tests.

Any evaluation should include a careful history of past and present symptoms with an examination. Medical tests that simply look for existing damage are not a substitute for controlling exposures. Also, since smoking can cause heart disease as well as lung cancer, emphysema, and other known respiratory prob-

lems, smokers exposure to magnesium may experience symptoms more rapidly than non-smokers under the same conditions of exposure. Prudent risk management requires careful consideration of *all* factors which may be causing exposure symptoms in the workplace.

Other methods to reduce exposure include:

- Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not used, respiratory protection should be mandatory.
- Always ensure that proper protective clothing is worn when using chemical substances. Proper maintenance and care of protective equipment is essential to its proper function.
- Wash thoroughly immediately after exposure to magnesium and at the end of the work shift or before eating, drinking, or smoking.
- Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of magnesium should be communicated to all exposed and potentially exposed workers.
- Eye wash stations should be provided in the immediate work area for emergency use. If there is a possibility of skin exposure to magnesium, emergency shower facilities should be provided.
- Workers whose clothing has been contaminated by magnesium should change into clean clothes before leaving work. Contaminated work clothing should be laundered only by individuals who have been informed of the hazards of exposure to magnesium.

RISK ASSESSMENT: ENVIRONMENT

General Assessment

As a naturally occurring mineral, magnesium poses very little threat to the environment. However, accidental spills or releases to the environment can occur during transportation, storage, disposal, or destruction of magnesium. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance. Accidental spills, large or small, where magnesium contacts incompatible commodities can result in release of toxic products (depending upon conditions of spill), and possible

contamination of the surrounding environmental mediums (water, soil, and air).

Magnesium is considered a combustible solid. Finely divided dusts and powders may create an explosive mixture in air, in contact with moisture, oxidizing materials, or in contact with an ignition source. It reacts with water, moisture, and acids to evolve explosive hydrogen gas. It is also incompatible with many other materials, including chlorinated solvents, methanol, hydrogen peroxide, sulfur compounds, animal and vegetable oils, the oxides, salts, and cyanides of other metals, and even oxygen. Extreme caution is required in handling, storage, transportation, and disposal of magnesium. These characteristics also require special consideration during any emergency situation involving a leak or spill of magnesium powder or dust. Should magnesium ever come into contact with these various incompatible substances either during use, transportation, storage, or disposal, violent and even explosive reactions are possible.

Magnesium occurs naturally in the environment (terrestrial soils and aquatic sediments) and may enter the environment as a result of industrial and municipal waste treatment plant discharges and from spills.

☠ *Acute Ecological Effects*

Acute (short-term) toxic effects may include the death of animals, birds, or fish and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to magnesium.

Magnesium and its salts have slight acute toxicity to aquatic life. Insufficient data are available to evaluate the short-term effects of magnesium to plants, birds, or land animals. However, it should be noted that the U.S. Environmental Protection Agency does NOT list magnesium as a hazardous substance.

🕒 *Chronic Ecological Effects*

Chronic (long-term) toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals.

Magnesium and its salts have slight chronic toxicity to aquatic life. Insufficient data are available to evaluate or predict the long-term effects of magnesium to plants, birds, or land animals. However, it should be noted that the U.S. Environmental Protection Agency does NOT list magnesium as a hazardous substance.

💧 *Water Solubility*

Magnesium is nearly insoluble (0.01%) in water. Concentrations of less than 1 milligram may mix with a liter of water.

🕒 *Persistence in the Environment*

Magnesium is highly persistent in water, with a half-life greater than 200 days. The half-life of a pollutant is the amount of time it takes for one half of the chemical to be degraded. Magnesium is also naturally present in terrestrial soils and aquatic sediments.

🐟 *Bioaccumulation in Aquatic Organisms*

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans.

The concentration of magnesium found in fish tissues is expected to be about the same as the average concentration of magnesium in the water from which the fish was taken.

🛑 *Recommended Risk-Reduction Measures*

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in a leak or spill of magnesium dusts or powders into the environment. The correct use of labeling on all containers, trucks, and rail cars will enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of magnesium should be segregated from incompatible chemicals to minimize the risk of cross-contamination or contact. Care should be taken to prevent physical damage to storage containers. Also, dusty conditions must be avoided in storage and use areas. When magnesium comes into contact with water or acids, it will readily liberate excessive amounts of highly flammable and explosive hydrogen gas.

If a spill or leak to the environment has occurred, fire department, emergency response and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those trained in proper spill containment procedures using non-sparking tools. Contaminated soils should be removed for decontamination and replaced with clean soil. If magnesium should contact the water table, aquifer, or navigable waterway, time is of the essence. It is only slightly soluble and total remediation may be

possible. The local and/or state emergency response authorities may require notification. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of magnesium.

If magnesium is spilled or leaked, the following specific steps are recommended:

- Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened for normal work.
- Remove all ignition sources from area.
- Ventilate area of spill or leak.
- Collect powdered materials in the safest manner possible and deposit in sealed containers. Recommend using a vacuum equipped with a high-efficiency particulate air (HEPA) filter. Do not dry sweep (generates airborne dusts). Keep water away (do NOT damp mop residues).
- It may be necessary to dispose of magnesium as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving magnesium can present a significant threat to business operations. The loss or damage of equipment or facilities can significantly affect fiscal viability. Lawsuits that may result from personnel injury/death, public exposures, and/or environmental contamination will also require a serious expenditure of resources. Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business.

Recommended Risk-Reduction Measures

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures for responding to chemical incidents. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

| 1 | 0 | 0 | | 0 = Minimum Hazard 1 = Slight Hazard 2 = Moderate Hazard 3 = Serious Hazard 4 = Severe Hazard | HEALTH = BLUE FIRE = RED REACTIVITY = YELLOW OTHER = WHITE | OX = Oxidizer ACID = Acid ALK = Alkali COR = Corrosive W = Use No Water |

SECTION I - GENERAL INFORMATION

| | | |
|---|--|------------------------------------|
| Characterization Magnesium Compound | RCRA Number None | EPA Class Not Applicable |
| DOT Proper Shipping Name Not Listed | Chemical Abstract Service (CAS) Number 7786-30-3 | |
| DOT Hazard Class and Label Requirements No Citation | DOT Emergency Guide Code No Citation | |
| DOT Identification Number No Citation | Atomic Formula MgCl₂ | |

Synonyms

Magnogene; dus-top.

SECTION II - HAZARDOUS INGREDIENTS AND IDENTITY INFORMATION

| Hazardous Components (specific identity) | OSHA Exposure Criteria | NIOSH Exposure Criteria | Immediately Dangerous to Life and Health (IDLH) | ACGIH Exposure Criteria |
|---|---|---|---|---|
| Magnesium chloride (derivation: By action of hydrochloric acid on magnesium oxide or hydroxide, especially the latter when precipitated from sea water). | PEL: Not Established STEL: Not Established | REL: Not Established STEL: Not Established | Not Determined | TLV: Not Established STEL: Not Established |

SECTION III - PHYSICAL AND CHEMICAL CHARACTERISTICS

| | |
|--|---|
| Boiling Point 2574°F (1412°C) Decomposes | Specific Gravity (H ₂ O = 1) 2.4 |
| Vapor Pressure (mm Hg) Not Found | Molecular Weight 95.21 |
| Vapor Density (Air = 1) Not Found | Melting Point 1314°F (712°C) |

Solubility

Soluble in water (evolves excessive heat) and alcohol.

Appearance and Odor

Soft, white, deliquescent, crystalline solid with no detectable odor.

SECTION IV - FIRE AND EXPLOSION HAZARD DATA

| | |
|--|--|
| Flash Point (method used) Not Determined | Explosive Limits in Air % by Volume LEL: Not Applicable UEL: Not Applicable |
| NFPA Classification Non-Flammable Solid | Autoignition Temperature Not Determined |

Extinguishing Media

Use agent suitable to surrounding fire. Do NOT use water (reaction is exothermic). Dry chemical or foam may suffice for small fires. For large fires, try fog or regular foam.

Special Fire Fighting Procedures

Poisonous gases are produced in fire. Wear full protective clothing and self-contained breathing apparatus (SCBA). Only use a water spray to keep fire-exposed containers cool. Do NOT get water inside containers. Do NOT release runoff from fire-fighting measures to sewers or waterways.

Unusual Fire and Explosion Hazards

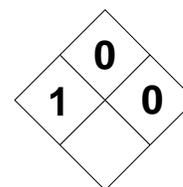

Can release extreme heat when wet or upon contact with incompatible materials. When combined with some incompatible materials, explosion and fire can be severe.

| SECTION V - REACTIVITY DATA | | | | |
|--|---|---|------------------------------|---|
| Stability | | Conditions to Avoid Magnesium chloride is stable under normal conditions of temperature and pressure. Because it will readily absorb moisture, containers must be kept tightly closed. Keep away from incompatible materials. | | |
| Stable X | Unstable | Incompatibility (materials to avoid) Incompatible with 2-furan percarboxylic acid. Also, in humid environments, magnesium chloride can cause steel to rust rapidly. | | |
| Hazardous Polymerization | | Conditions to Avoid Under normal conditions of temperature and pressure, hazardous polymerization of magnesium chloride is not known to occur. | | |
| May Occur | Will Not Occur X | Hazardous Decomposition or By-products When heated to decomposition, magnesium chloride can emit toxic/poisonous fumes and gases. These include toxic chloride fumes, magnesium fumes, and oxides of chlorine. | | |
| SECTION VI - HEALTH HAZARD DATA | | | | |
| Primary Route(s) of Entry: | | Inhalation? X | Absorption (skin)? | Ingestion? X |
| Health Hazards INHALATION: The dusts can produce irritation of the eyes and mucous membranes. There may be cough, congestion, and other symptoms of respiratory system irritation. Some of the irritant effects resemble that of simple mechanical irritation (a nuisance dust). EYES & SKIN: Causes skin sores that resist healing and accumulate gas under the skin (small blisters). INGESTION: Large doses can cause gastrointestinal irritation and other unspecified effects. | | | | |
| Carcinogenicity Unknown Human Unknown Animal | NTP Listed? No | IARC Cancer Review Group? No | OSHA Regulated? No | Target Organs? Skin, eyes, and respiratory system (mucosa). |
| Medical Conditions Generally Aggravated by Exposure None reported. | | | | |
| Emergency and First-aid Procedures Eye contact: Flush immediately with water for 15 minutes (minimum); seek medical attention. Skin contact: Remove all contaminated clothing. Immediately wash area with large amounts of soap and water. For inhalation: Remove the person from exposure. Provide respiratory assistance and CPR. Transfer to medical facility. If swallowed: Provide breathing assistance if necessary. Never attempt to give a convulsing or unconscious person anything by mouth. If victim is conscious, give 1-2 glasses of water to dilute and induce vomiting with Syrup of Ipecac. Seek medical attention immediately. | | | | |
| SECTION VII - PRECAUTIONS FOR SAFE HANDLING AND USE | | | | |
| Steps to be Taken in Case Material is Released or Spilled Collect powdered material in most convenient manner possible and deposit in sealed drum. Keep those not involved in cleanup from entering area. Do NOT dry sweep (creates airborne dusts). Use a vacuum equipped with a high-efficiency particulate air (HEPA) filter. Do NOT use water. | | | | |
| Preferred Waste Disposal Method No citation. | | | | |
| Precautions to be Taken in Handling and Storage Store in tightly closed containers in cool, well-ventilated area. Sources of ignition are prohibited where magnesium chloride is stored. Keep away from water. Storage with desiccant is recommended. | | | | |
| Other Precautions and Warnings Outside or detached storage facility is recommended. Protect containers from physical damage. | | | | |
| SECTION VIII - CONTROL MEASURES AND PERSONAL PROTECTIVE EQUIPMENT | | | | |
| Respiratory Protection (specify type) No exposure levels established. For best protection, use a supplied-air respirator with a full facepiece, hood, or helmet or a self-contained breathing apparatus (SCBA) operated in positive pressure mode. | | | | |
| Ventilation Local exhaust or general mechanical systems recommended. | | | | |
| Protective Gloves Impervious Material | Eye Protection Chemical/Dust Goggles or Face Mask | Other Protective Clothing Protective Suit or Clothing | | |
| Work/Hygiene Practices Always wash hands thoroughly after using chemical; never bring food, drink, or smoking materials into vicinity of chemicals. | | | | |

MAGNESIUM CHLORIDE

MgCl₂

CAS: 7786-30-3

IDENTIFICATION AND TYPICAL USES

Magnesium chloride appears as a soft, white, deliquescent, crystalline solid with no detectable odor. Used as a source of magnesium metal, in disinfectants, in fire extinguishers, for fire-proofing wood, in the manufacture of magnesium oxychloride cement, in refrigerating brines, in the manufacture of ceramics, for cooling drilling tools, in the textile industry, in the manufacture of parchment paper, in floor sweeping compounds, as a flocculating agent, and as a catalyst.

RISK ASSESSMENT: HEALTH

General Assessment

Magnesium chloride is moderately toxic by *ingestion* and *inhalation*. Skin contact with a solution of magnesium chloride is also dangerous due to the corrosive and destructive nature of this compound (absorption has not been reported as an entry route). Its carcinogenic potential is not clearly understood in the references. Some mutation data have been reported.

Inhalation of solution vapors causes sneezing, cough, and irritation of the nose and throat. There may be lachrymation (tearing), and a burning sensation in the nasal cavity often accompanied by nosebleeds. Inhalation of the dusts and particles of magnesium can irritate the eyes and nasal passages. Magnesium may react with the water content in the bronchial passages to form caustic magnesium hydroxide which can cause severe burns and tissue damage.

Magnesium chloride particles that become imbedded in the skin can cause the development of slow healing sores and gaseous blebs (small blisters). Skin contact with a concentrated solution causes irritation, inflammation, and the appearance of small ulcerations on the skin's surface. There may be erythema (redness) and possible peeling of the facial skin. Eye contact will cause tearing and inflammation of the eyelids.

☠ *Acute Health Effects*

The following acute (short-term) health effects may occur immediately or shortly after exposure to magnesium chloride:

Skin: Irritation, rash, and possible redness and the appearance of small blisters.

Eye: Irritation, inflammation, watering, and swelling.

Lung: Inhalation of magnesium chloride dusts may cause irritation of the mucous membranes in the respiratory tract. There may be burning in the nasal cavity with nosebleeds.

☘ *Chronic Health Effects*

The following chronic (long-term) health effects may occur at some time after exposure to magnesium chloride and can last for months or even years:

Cancer Hazards: According to the information presented in the references, magnesium chloride has not been adequately tested for its ability to cause cancer in test animals. The data are conflicting and inconclusive in this regard. Mutation (causes genetic changes) data have been documented and many scientists believe that such chemicals may pose a cancer risk in the long-term. Additional study and research is required.

Reproductive Hazard: According to information available in the references, magnesium chloride has not been adequately tested for its ability to adversely affect reproduction in laboratory animals.

🛡 *Recommended Risk-Reduction Measures*

Personnel should avoid direct contact with magnesium chloride. If a less toxic chemical cannot be substituted for a hazardous material, then *engineering controls* are the most effective method of reducing exposures.

The best protection is to enclose operations and/or provide local exhaust ventilation at the site of chemical release. While not always operationally feasible, isolating operations can also reduce exposure. Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around magnesium chloride. No exposure levels have been established for magnesium chloride. This does not mean that exposure is without health risk. A full facepiece respirator equipped with a high efficiency particulate air (HEPA) filter equipped with a dust/mist/fume pre-filter may suffice. However, for the best protection use a supplied-air respirator with a full facepiece operated in positive pressure mode or an MSHA/NIOSH-approved self-contained breathing apparatus (SCBA) with full facepiece operated in pressure demand or other continuous flow mode. If a full facepiece is not available, then chemical/dust goggles should be worn to protect the eyes. Whenever a chemical dust hazard exists, a face shield and a protective apron should be worn. To prevent hand and skin exposures, impervious rubber gloves should be used. Glove manufacturers should be contacted and permeation studies obtained *before* final glove selections are made.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with magnesium chloride dusts or solutions.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where magnesium chloride is used or stored.

If symptoms develop or overexposure is suspected, the following may also be useful:

- Urine and serum magnesium levels.
- Lung function tests.
- Consider chest X-ray after acute overexposure.

Any evaluation should include a careful history of past and present symptoms with a medical examination. Medical tests that look for damage already done are not a substitute for controlling exposure. Also, since smoking can cause heart disease, emphysema, and a number of other respiratory disorders, smokers exposed to lung irritants such as magnesium chloride dusts and fumes may experience symptoms much more quickly than non-smokers under the same condi-

tions of exposure. Prudent risk management requires proper consideration of *all* factors which may be causing the appearance of exposures symptoms in the work place.

Other methods to reduce exposure include:

- Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not used, respiratory protection should be mandatory.
- Always ensure that proper protective clothing is worn when using chemical substances and that personnel are trained in its use and care.
- Wash thoroughly immediately after exposure to magnesium chloride and at the end of the work shift or before eating, drinking, or smoking.
- Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of magnesium chloride should be communicated to all exposed and potentially exposed workers.
- Eye wash stations and emergency showers should be located in the immediate work area.
- Work clothing that has been contaminated with magnesium chloride should never be worn home where family members can be exposed as well. Contaminated clothing should be laundered at work or by an authorized service by personnel who have been trained in the hazards associated with exposure to magnesium chloride.

RISK ASSESSMENT: ENVIRONMENT

General Assessment

The environment is at risk of exposure during transportation, storage, disposal, or destruction of magnesium chloride. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance. Accidental spills, large or small, can result in fire, explosion, and possible contamination of the surrounding environmental mediums (water, soil, and air).

Magnesium chloride may react violently in contact with many common acids. Reactions with water and moisture will evolve extreme heat. In a fire, magnesium chloride will emit toxic and poisonous gases. These characteristics require special consideration during any emergency situation involving a leak or spill of magnesium chloride.

Magnesium chloride can enter the environment through industrial discharge, spills, or leaks.

☠ *Acute Ecological Effects*

Acute (short-term) toxic effects may include the death of animals, birds, or fish and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to magnesium chloride. Insufficient data are available to evaluate the short-term effects of magnesium chloride exposure to aquatic life, plants, birds or land animals.

🕒 *Chronic Ecological Effects*

Chronic (long-term) toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals. Insufficient data are available to evaluate the long-term effects of magnesium chloride exposure to aquatic life, plants, birds or land animals.

💧 *Water Solubility*

Magnesium chloride is soluble in water, decomposing and producing heat. Concentrations of 1000 milligrams or more will mix with a liter of water.

🕒 *Persistence in the Environment*

Magnesium chloride is only slightly persistent in the aquatic environment, with a half-life of less than 2 days. The half-life of a pollutant is the amount of time it takes for one half of the chemical to be degraded.

🌊 *Bioaccumulation in Aquatic Organisms*

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans.

The concentration of magnesium chloride found in fish is expected to be much lower than the average concentration of magnesium chloride in the water from which the fish was taken.

🛡️ *Recommended Risk-Reduction Measures*

Proper training of all transporters will reduce the likelihood of a mishap or accidents resulting in a leak or spill to the environment. Proper labeling on all con-

tainers, trucks, and rail cars will enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

If a spill or leak to the environment has occurred, fire department, emergency response and/or hazardous materials spill personnel should be notified immediately. Do not dry sweep. When vacuuming, a high efficiency particulate air (HEPA) filter should be used, not a standard shop vacuum. Do NOT use water to rinse residue. Deposit collected materials in sealed, moisture-free drums for disposal. Cleanup should be attempted only by those trained in proper spill containment procedures. Contaminated soils may need to be removed and replaced with clean soil. If magnesium chloride should contact the water table, aquifer, or navigable waterway, time is of the essence. Magnesium chloride is soluble in water and will decompose. Therefore, total containment and remediation may not be possible. When such spills occur, the local and/or state emergency response authorities should be notified. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of magnesium chloride. If magnesium chloride is spilled or leaked, the following specific steps are recommended:

- ☑ Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened for normal work.
- ☑ Ventilate area of spill or leak and remove all ignition sources.
- ☑ Collect powdered materials in most convenient and safe manner possible and place in sealed drums for disposal. Do NOT dry sweep; use HEPA vacuum instead. Do NOT use water to clean residue or damp mop.
- ☑ It may be necessary to dispose of magnesium chloride as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving magnesium chloride can present a significant threat to business operations. The loss or damage of equipment or facilities can significantly affect fiscal viability. Lawsuits that may

result from personnel injury/death, public exposures, and/or environmental contamination will also require a serious expenditure of resources. Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business.

🕒 Recommended Risk-Reduction Measures

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of such procedures dealing with safety or emergency response. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

MAGNESIUM HYDROXIDEH₂MgO₂

CAS: 1309-42-8

**IDENTIFICATION AND TYPICAL USES**

Magnesium hydroxide appears as a white odorless powder. It is an intermediate for obtaining magnesium metal, in the refining of sugar, in medicine (antacids, laxatives), as a residual fuel oil additive, in sulfite pulp, in uranium processing, in the making of dentifrice, in foods (as a drying agent and for color retention) and in frozen desserts.

RISK ASSESSMENT: HEALTH**General Assessment**

Magnesium hydroxide exhibits relatively low toxicity in humans by *inhalation* and *ingestion*. It is generally considered a nuisance particulate. However, exposure to sufficient quantities, especially by ingestion, can pose a serious health risk. There is no information on its carcinogenic, mutagenic, or teratogenic capabilities.

Inhalation causes irritation to the eyes, nose, throat, and mucosa of the upper respiratory tract with cough and congestion. If ingested, magnesium salts will be slowly absorbed. However, large amounts can cause systemic poisoning. Elevated blood magnesium levels may cause a drop in blood pressure, pulse, and respiration. Other symptoms include diarrhea, constipation, abdominal distention, intestinal blockage, possible kidney effects, and depression of the central nervous system (CNS). This can lead to failed reflexes with progression to respiratory failure or cardiac arrest and death.

☠ Acute Health Effects

The following acute (short-term) health effects may occur immediately or shortly after human exposure to magnesium hydroxide:

Skin: May cause mild irritation, depending on the conditions and length of exposure.

Eye: Mild to moderate irritation.

Lung: Irritation of the mucosa of the eyes, nose, throat, and respiratory tract.

Other: Ingestion of excessive quantities of magnesium hydroxide can cause gastrointestinal effects, kidney problems, and depression of the central nervous system that can lead to death.

☞ Chronic Health Effects

The following chronic (long-term) health effects may occur at some time after exposure to magnesium hydroxide and can last for months or even years:

Cancer Hazards: According to information presented in the references, magnesium hydroxide has not been shown to cause cancer in animals.

Reproductive Hazard: According to information presented in the references, there are no reports of any teratogenic or reproductive effects resulting from exposure to magnesium hydroxide.

Other Chronic Effects: Repeated or prolonged contact may cause chronic gastrointestinal problems and may lead to kidney dysfunction.

☞ Recommended Risk-Reduction Measures

Even though the toxicity of magnesium hydroxide is considered to be relatively low, personnel should avoid direct contact with magnesium hydroxide. If a less toxic material or compound cannot be substituted for magnesium hydroxide, then *engineering controls* are the most effective method of reducing exposures. The best protection is to enclose operations and/or provide local exhaust ventilation at the site of magnesium hydroxide dust release. While not always operationally feasible, isolating operations can also reduce exposure. Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around magnesium hydroxide. A supplied-air respirator operated in continuous flow mode or a self-contained breathing appa-

ratus (SCBA) with full facepiece operated in pressure demand are recommended for the greatest possible respiratory protection. However, for low or infrequent exposure, an MSHA/NIOSH-approved full facepiece respirator with a high efficiency particulate air (HEPA) filter may be used. If a full facepiece is not available, then chemical/dust goggles should be worn to protect the eyes. A face shield and protective apron should also be worn. To prevent hand and skin exposures, gloves should be used.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with magnesium hydroxide.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where magnesium hydroxide is used or stored.

Before beginning employment working with magnesium hydroxide, and at regular intervals thereafter (e.g., annually), those personnel with frequent or potentially high exposures should be provided the following recommended medical tests:

- Kidney function tests (establish baseline).

If symptoms develop or overexposure is suspected, consider the following additional tests:

- Kidney function tests (compare to baseline).
- Magnesium serum levels.
- Lung function tests.

Any evaluation should include a careful history of past and present symptoms with an examination. Medical tests that simply look for existing damage are not a substitute for controlling exposures. Also, since smoking can cause heart disease as well as lung cancer, emphysema, and other known respiratory problems, smokers exposure to magnesium hydroxide may experience symptoms more rapidly than non-smokers under the same conditions of exposure. Prudent risk management requires careful consideration of *all* factors which may be causing exposure symptoms in the workplace.

Other methods to reduce exposure include:

- Where possible, enclose operations and use local exhaust ventilation at the site of chemical release.

If local exhaust ventilation or enclosure is not used, respiratory protection should be mandatory.

- Always ensure that proper protective clothing is worn when using chemical substances. Proper maintenance and care of protective equipment is essential to its proper function.
- Wash thoroughly immediately after exposure to magnesium hydroxide and at the end of the work shift or before eating, drinking, or smoking.
- Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of magnesium hydroxide should be communicated to all exposed and potentially exposed workers.
- Eye wash stations should be provided in the immediate work area for emergency use. If there is a possibility of skin exposure to magnesium hydroxide, emergency shower facilities should be provided in the immediate area.
- Workers whose clothing has been contaminated by magnesium hydroxide should change into clean clothes before leaving work. Contaminated work clothing should be laundered only by individuals who have been informed of the hazards of exposure to magnesium hydroxide.

RISK ASSESSMENT: ENVIRONMENT

General Assessment

As a naturally occurring mineral, magnesium poses very little threat to the environment. However, accidental spills or releases of magnesium hydroxide to the environment can occur during transportation, storage, disposal, or destruction of magnesium hydroxide. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance. Accidental spills, large or small, where magnesium hydroxide contacts incompatible commodities can result in release of toxic products (depending upon conditions of spill), and possible contamination of the surrounding environmental mediums (water, soil, and air).

Magnesium hydroxide is considered a non-combustible solid. It is incompatible with maleic anhydride, sodium hydroxide, and phosphorus, and extreme caution is required in handling, storage, transportation, and disposal of magnesium hydroxide. These characteristics also require special considera-

tion during any emergency situation involving a leak or spill of magnesium hydroxide powder or dust. Should magnesium hydroxide ever come into contact with incompatible substances either during use, transportation, storage, or disposal, violent and even explosive reactions are possible.

Magnesium hydroxide may enter the environment as a result of industrial and municipal waste treatment plant discharges and from spills.

☠ *Acute Ecological Effects*

Acute (short-term) toxic effects may include the death of animals, birds, or fish and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to magnesium hydroxide. Magnesium and its salts have slight acute toxicity to aquatic life. Insufficient data are available to evaluate the short-term effects of magnesium hydroxide to plants, birds, or land animals.

☞ *Chronic Ecological Effects*

Chronic (long-term) toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals. Magnesium and its salts have slight chronic toxicity to aquatic life. Insufficient data are available to evaluate or predict the long-term effects of magnesium hydroxide to plants, birds, or land animals.

💧 *Water Solubility*

Magnesium hydroxide is nearly insoluble (0.01%) in water. Concentrations of less than 1 milligram may mix with a liter of water.

⌚ *Persistence in the Environment*

Magnesium is highly persistent in water, with a half-life greater than 200 days. The half-life of a pollutant is the amount of time it takes for one half of the chemical to be degraded. Magnesium is also naturally present in soils, with its three hydrates (barrington, nesquehonite, and landsforite).

🌊 *Bioaccumulation in Aquatic Organisms*

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become con-

centrated in the tissues and internal organs of animals as well as humans.

The concentration of magnesium hydroxide found in fish tissues is expected to be about the same as the average concentration of magnesium hydroxide in the water from which the fish was taken.

🛑 *Recommended Risk-Reduction Measures*

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in a leak or spill of magnesium hydroxide dusts or powders into the environment. The correct use of labeling on all containers, trucks, and rail cars will enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of magnesium hydroxide should be segregated from incompatible chemicals to minimize the risk of cross-contamination or contact. Care should be taken to prevent physical damage to storage containers. Also, dusty conditions must be avoided in storage and use areas.

If a spill or leak to the environment has occurred, fire department, emergency response and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those trained in proper spill containment procedures. Contaminated soils should be removed for decontamination and replaced with clean soil. If magnesium hydroxide should contact the water table, aquifer, or navigable waterway, time is of the essence. It is slightly soluble and total remediation may not be possible. The local and/or state emergency response authorities may require notification. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of magnesium hydroxide.

If magnesium hydroxide is spilled or leaked, the following specific steps are recommended:

- ☑ Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened for normal work.
- ☑ Remove all ignition sources from area.
- ☑ Ventilate area of spill or leak.
- ☑ Collect powdered materials in the safest manner possible and deposit in sealed containers. Recommend using a vacuum equipped with a high-efficiency particulate air (HEPA) filter. Do not dry sweep (generates airborne dusts). Damp mop

residues and collect for disposal. Water spray can be used to knock down vapors. Runoff should also be collected for disposal.

- ☑ It may be necessary to dispose of magnesium hydroxide as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving magnesium hydroxide can present a significant threat to business operations. The loss or damage of equipment or facilities can significantly affect fiscal viability. Lawsuits that may result from personnel injury/death, public exposures, and/or environmental contamination will also require a serious expenditure of resources. Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business.

Recommended Risk-Reduction Measures

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures for responding to chemical incidents. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

It may react with the water content in the bronchial passages to form caustic magnesium hydroxide which can damage the lungs. Inhalation of the fumes can cause metal fume fever with symptoms of cough, pressure in chest, leukocytosis, chills, and other febrile (feverish) conditions. EYES & SKIN: Causes skin sores that resist healing and accumulate gas under the skin (small blisters). The powder metal ignites easily on moist skin and eyes causing serious burns. INGESTION: Large doses can cause gastrointestinal irritation and other unspecified effects. | | | | |
| Carcinogenicity Unknown Human Unknown Animal | NTP Listed? No | IARC Cancer Review Group? No | OSHA Regulated? No | Target Organs? Respiratory system, eyes, skin, CNS, kidneys. |
| Medical Conditions Generally Aggravated by Exposure Existing kidney dysfunction may be aggravated by ingestion of magnesium salts. | | | | |
| Emergency and First-aid Procedures Eye contact: Do not allow victim to keep eyes tightly shut. Flush immediately with water for 15 minutes (minimum); seek medical attention. Skin contact: Remove all contaminated clothing. Immediately wash area with flooding amounts of water. For reddened or blistered skin, seek medical assistance. For inhalation: Remove the person from exposure. Provide respiratory assistance and CPR. Transfer to medical facility. If swallowed: Seek medical attention. Give 1 to 2 glasses of water to dilute. Never give anything by mouth to an unconscious or convulsing person. | | | | |
| SECTION VII - PRECAUTIONS FOR SAFE HANDLING AND USE | | | | |
| Steps to be Taken in Case Material is Released or Spilled Collect powdered materials in most convenient and safe manner and deposit in sealed containers. Dry sweep not recommended. Use HEPA vacuum. Ventilate area of spill. Flush residue with flooding amounts of water and collect. Restrict those not involved in cleanup from entering area. | | | | |
| Preferred Waste Disposal Method No citation. | | | | |
| Precautions to be Taken in Handling and Storage Store to avoid contact with incompatible materials. Prevent physical damage to containers. Keep containers tightly closed (air-tight) to prevent contact with moisture. | | | | |
| Other Precautions and Warnings Avoid excessive dust generation in storage and handling areas. Personnel should be trained on the proper precautions for working with magnesium compounds before initial assignment. | | | | |
| SECTION VIII - CONTROL MEASURES AND PERSONAL PROTECTIVE EQUIPMENT | | | | |
| Respiratory Protection (<i>specify type</i>) For dust exposures over PEL, use a respirator with a high-efficiency particulate air (HEPA) filter; otherwise, use a self-contained breathing apparatus with full facepiece operated in positive pressure mode. | | | | |
| Ventilation Local exhaust (preferred) at site of chemical work or general ventilation. | | | | |
| Protective Gloves Impervious Material | Eye Protection Chemical/Dust Goggles or Face Mask | Other Protective Clothing Protective Apron, Boots | | |
| Work/Hygiene Practices Always wash hands thoroughly after using chemical; never bring food, drink, or smoking materials into vicinity of chemicals. | | | | |

MAGNESIUM OXIDE

MgO

CAS: 1309-48-4

**IDENTIFICATION AND TYPICAL USES**

Magnesium oxide appears as a finely divided white powder with no odor that can be dispersed in air as a fume when heated. It is used in the manufacture of steel linings, in the production of polycrystalline ceramic for aircraft windshields, in electrical insulation, in pharmaceuticals and cosmetics, as an accelerator in the making of inorganic rubber materials, in oxychloride and oxysulfate cements, in paper, in fertilizers, for removing sulfur dioxide from stack gases, in semiconductors, and as a food and feed additive.

RISK ASSESSMENT: HEALTH***General Assessment***

Magnesium oxide can enter the body and cause varying degrees of adverse health effects through *inhalation* and *ingestion*. There is no information on its teratogenic or mutagenic capabilities. While no agencies have listed magnesium oxide as a carcinogen, there is limited evidence that it has caused some development of tumors in test animals.

Inhalation of the dusts and particles of magnesium oxide can irritate the eyes and nasal passages. Magnesium oxide may react with the water content in the bronchial passages to form caustic magnesium hydroxide which can cause severe burns and tissue damage. Magnesium fumes in the oxide form can also irritate the eyes, nose, throat, and respiratory tract and may cause metal fume fever with cough, muscle pain, tightness and pressure in the chest, nausea, vomiting, chills, and other febrile (feverish) symptoms. These symptoms can begin 4 to 6 hours after exposure and persist for 24 hours. Leukocytosis (increase of leukocytes in the blood) may also develop.

Magnesium particles can become imbedded in the skin causing the development of slow healing sores and gaseous blebs (small blisters). If the skin is moist, burns may be serious and destructive.

Acute Health Effects

The following acute (short-term) health effects may occur immediately or shortly after human exposure to magnesium oxide:

Skin: May cause serious irritation and even burns, especially if the skin is moist. Small blisters can develop that will heal slowly and may become infected.

Eye: Severe irritation and possible burns due to the eyes' moisture content. Damage can be serious and permanent.

Lung: Irritation of the mucosa of the eyes, nose, throat, and respiratory tract.

CNS: Breathing heated fumes can cause metal fume fever with specific action on the central nervous system.

Chronic Health Effects

The following chronic (long-term) health effects may occur at some time after exposure to magnesium oxide and can last for months or even years:

Cancer Hazards: According to the references, magnesium oxide has been shown to cause tumors in experimental test animals. Its human carcinogenicity is not known.

Reproductive Hazard: According to the references, there are no reports of any teratogenic or reproductive effects resulting from exposure to magnesium oxide.

Other Chronic Effects: None reported.

Recommended Risk-Reduction Measures

Even though the toxicity of magnesium oxide is considered to be relatively low, personnel should avoid direct contact with magnesium oxide. If a less toxic material or compound cannot be substituted for magnesium oxide, then *engineering controls* are the most effective method of reducing exposures. The best protection is to enclose operations and/or provide lo-

cal exhaust ventilation at the site of magnesium oxide dust release. While not always operationally feasible, isolating operations can also reduce exposure. Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around magnesium oxide. A supplied-air respirator operated in continuous flow mode or a self-contained breathing apparatus (SCBA) with full facepiece operated in pressure demand are recommended for the best possible respiratory protection. However, for low or infrequent exposure, an MSHA/NIOSH-approved full facepiece respirator with a high-efficiency particulate air (HEPA) filter may be used. If a full facepiece is not available, then chemical/dust goggles should be worn to protect the eyes. A face shield and protective apron should also be used. To prevent hand and skin exposures, gloves should be used.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with magnesium oxide.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where magnesium oxide is used or stored.

Before beginning employment working with magnesium oxide, and at regular intervals thereafter (e.g., annually), those personnel with frequent or potentially high exposures should be provided the following recommended medical tests:

- Kidney function tests (establish baseline).

If symptoms develop or overexposure is suspected, consider the following additional tests:

- Kidney function tests (compare to baseline).
- Magnesium serum levels.
- Lung function tests.

Any evaluation should include a careful history of past and present symptoms with an examination. Medical tests that simply look for existing damage are not a substitute for controlling exposures. Also, since smoking can cause heart disease as well as lung cancer, emphysema, and other known respiratory problems, smokers exposure to magnesium oxide may experience symptoms more rapidly than non-smokers under the same conditions of exposure. Prudent risk management requires careful consideration of *all* fac-

tors which may be causing exposure symptoms in the workplace.

Other methods to reduce exposure include:

- Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not used, respiratory protection should be mandatory.
- Always ensure that proper protective clothing is worn when using chemical substances. Proper maintenance and care of protective equipment is essential to its proper function.
- Wash thoroughly immediately after exposure to magnesium oxide and at the end of the work shift or before eating, drinking, or smoking.
- Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of magnesium oxide should be communicated to all exposed and potentially exposed workers.
- Eye wash stations should be provided in the immediate work area for emergency use. If there is a possibility of skin exposure to magnesium oxide, emergency shower facilities should be provided.
- Workers whose clothing has been contaminated by magnesium oxide should change into clean clothes before leaving work. Contaminated work clothing should be laundered only by individuals who have been informed of the hazards of exposure to magnesium oxide.

RISK ASSESSMENT: ENVIRONMENT

General Assessment

As the naturally occurring mineral periclase, magnesium oxide poses very little threat to the environment. However, accidental spills or releases to the environment can occur during transportation, storage, disposal, or destruction of magnesium oxide. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance. Accidental spills, large or small, where magnesium oxide contacts incompatible commodities can result in release of toxic products (depending upon conditions of spill), and possible contamination of the surrounding environmental mediums (water, soil, and air).

Magnesium oxide is considered a non-combustible solid. However, finely divided dusts and powders

may create an explosive mixture in air in closed spaces. It is incompatible and reacts violently with many interhalogen compounds, including chlorine trifluoride and bromine trifluoride, and extreme caution is required in handling, storage, transportation, and disposal of magnesium oxide. These characteristics also require special consideration during any emergency situation involving a leak or spill of magnesium oxide powder or dust. Should magnesium oxide ever come into contact with incompatible substances either during use, transportation, storage, or disposal, violent and even explosive reactions are possible.

Magnesium oxide may enter the environment as a result of industrial and municipal waste treatment plant discharges and from spills.

☠ *Acute Ecological Effects*

Acute (short-term) toxic effects may include the death of animals, birds, or fish and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to magnesium oxide. Magnesium and its salts have slight acute toxicity to aquatic life. Insufficient data are available to evaluate the short-term effects of magnesium oxide to plants, birds, or land animals.

🕒 *Chronic Ecological Effects*

Chronic (long-term) toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals. Magnesium and its salts have slight chronic toxicity to aquatic life. Insufficient data are available to evaluate or predict the long-term effects of magnesium oxide to plants, birds, or land animals.

💧 *Water Solubility*

Magnesium oxide is nearly insoluble (0.009% at 86°F) in water. Concentrations of less than 1 milligram may mix with a liter of water. It will react in water to evolve magnesium hydroxide, a caustic.

🕒 *Persistence in the Environment*

Magnesium oxide is highly persistent in water, with a half-life greater than 200 days. The half-life of a pollutant is the amount of time it takes for one half of the chemical to be degraded. Magnesium oxide is also naturally present in terrestrial soils and aquatic sediments as the mineral periclase.

🐟 *Bioaccumulation in Aquatic Organisms*

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans.

The concentration of magnesium found in fish tissues is expected to be about the same as the average concentration of magnesium in the water from which the fish was taken.

🛑 *Recommended Risk-Reduction Measures*

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in a leak or spill of magnesium oxide dusts or powders into the environment. The correct use of labeling on all containers, trucks, and rail cars will enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of magnesium oxide should be segregated from incompatible chemicals to minimize the risk of cross-contamination or contact. Care should be taken to prevent physical damage to storage containers. Also, dusty conditions must be avoided in storage and use areas. Water and moisture should be kept away.

If a spill or leak to the environment has occurred, fire department, emergency response and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those trained in proper spill containment procedures. Contaminated soils should be removed for decontamination and replaced with clean soil. If magnesium oxide should contact the water table, aquifer, or navigable waterway, time is of the essence. It is slightly soluble and total remediation may not be possible. The local and/or state emergency response authorities should be notified. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of magnesium compounds.

If magnesium oxide is spilled or leaked, the following specific steps are recommended:

- Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened for normal work.
- Remove all ignition sources and ventilate area of spill or leak.
- Ventilate area of spill or leak.

- ☑ Collect powdered materials in the safest manner possible and deposit in sealed containers. Recommend using a vacuum equipped with a high-efficiency particulate air (HEPA) filter. Do not dry sweep (generates airborne dusts). Using flooding amounts of water to wash away residues. Runoff should also be collected for disposal.
- ☑ It may be necessary to dispose of magnesium oxide as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving magnesium oxide can present a significant threat to business operations. The loss or damage of equipment or facilities can significantly affect fiscal viability. Lawsuits that may result from personnel injury/death, public exposures, and/or environmental contamination will also require a serious expenditure of resources. Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business.

Recommended Risk-Reduction Measures

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures for responding to chemical incidents. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

| Primary Route(s) of Entry: | | Inhalation? X | Absorption (skin/eye)? | Ingestion? X |
| Health Hazards INHALATION: Toxicity is considered to be low, but excessive dust inhalation can cause irritation to the nose and mucous membranes of the eyes, nose, throat, and respiratory tract. EYES & SKIN: Exposure to the eyes and skin may cause mild irritation. INGESTION: Excessive doses may cause diarrhea, constipation, abdominal distention, obstruction of the intestine, and possible depression of the CNS with loss of reflexes, and progression to respiratory paralysis or cardiac arrest and death. Elevated serum magnesium levels may cause a drop in blood pressure, pulse, respiration, and mental status. | | | | |
| Carcinogenicity Unknown Human Unknown Animal | NTP Listed? No | IARC Cancer Review Group? No | OSHA Regulated? No | Target Organs? Respiratory system, eyes, skin, GI tract, CNS. |
| Medical Conditions Generally Aggravated by Exposure None reported. However, existing kidney disease is aggravated by ingestion of other magnesium salts. | | | | |
| Emergency and First-aid Procedures Eye contact: Do not allow victim to keep eyes tightly shut. Flush immediately with water for 15 minutes (minimum); seek medical attention. Skin contact: Remove all contaminated clothing. Immediately wash area with flooding amounts of water. For reddened or blistered skin, seek medical assistance. For inhalation: Remove the person from exposure. Provide respiratory assistance and CPR. Transfer to medical facility. If swallowed: Seek medical attention. Give 1 to 2 glasses of water to dilute. Vomiting may be spontaneous (without inducement). Never give anything by mouth to an unconscious or convulsing person. | | | | |
| SECTION VII - PRECAUTIONS FOR SAFE HANDLING AND USE | | | | |
| Steps to be Taken in Case Material is Released or Spilled Collect powdered materials in most convenient and safe manner and deposit in sealed containers. Dry sweep NOT recommended. Use HEPA vacuum. Damp mop residue and collect for disposal. Ventilate area of spill. Restrict those not involved in cleanup from entering area. Notify appropriate authorities. | | | | |
| Preferred Waste Disposal Method No citation. | | | | |
| Precautions to be Taken in Handling and Storage Store to avoid contact with incompatible materials. Prevent physical damage to containers. Keep containers tightly closed. | | | | |
| Other Precautions and Warnings Avoid excessive dust generation in storage and handling areas. Personnel should be trained on the proper precautions for working with magnesium compounds <i>before</i> initial assignment. | | | | |
| SECTION VIII - CONTROL MEASURES AND PERSONAL PROTECTIVE EQUIPMENT | | | | |
| Respiratory Protection (<i>specify type</i>) No exposure levels established: Use a respirator with a high-efficiency particulate air (HEPA) filter; otherwise, use a self-contained breathing apparatus with full facepiece operated in positive pressure mode. | | | | |
| Ventilation Local exhaust (preferred) at site of chemical work or general ventilation. | | | | |
| Protective Gloves Impervious Material | Eye Protection Chemical/Dust Goggles or Face Mask | Other Protective Clothing Protective Apron, Boots | | |
| Work/Hygiene Practices Always wash hands thoroughly after using chemical; never bring food, drink, or smoking materials into vicinity of chemicals. | | | | |

MAGNESIUM SULFATEMgSO₄

CAS: 7487-88-9

**IDENTIFICATION AND TYPICAL USES**

Magnesium sulfate appears as colorless or opaque needles, crystals, or powder with a cooling, saline, bitter taste, and no odor. It is used in the textile industry for warp-sizing and loading of cotton goods, weighting silk, dyeing, and calico printing. It is also used for fire-proofing other materials, in mineral waters, as a catalyst carrier, in ceramics, in fertilizers, for paper sizing, in certain cosmetic lotions, and as a dietary supplement.

RISK ASSESSMENT: HEALTH***General Assessment***

Because of its poor absorption, magnesium sulfate exhibits relatively low toxicity in humans by *inhalation* and *ingestion*. It is generally considered a nuisance particulate. However, exposure to sufficient quantities, especially by ingestion, can pose a serious health risk. There is no information on its carcinogenic, mutagenic, or teratogenic capabilities.

Inhalation causes mechanical (as opposed to chemical) irritation to the eyes, nose, throat, and mucosa of the upper respiratory tract. If ingested and sufficient quantities are absorbed, magnesium sulfate can cause systemic poisoning. Elevated blood magnesium levels may cause a drop in blood pressure, pulse, and respiration. Other symptoms include hypocalcemia (a deficiency in blood calcium levels), diarrhea, constipation, nausea, vomiting, intestinal blockage due to blocked bowel or loss of muscle contraction, and depression of the central nervous system (CNS). This can lead to flushing of the face, sweating, failed reflexes with progression to respiratory failure or cardiac arrest and death.

☠ *Acute Health Effects*

The following acute (short-term) health effects may occur immediately or shortly after human exposure to magnesium sulfate:

Skin: May cause mild irritation, depending on the conditions and length of exposure.

Eye: Mild to moderate irritation.

Lung: Mechanical irritation of the mucosa of the eyes, nose, throat, and respiratory tract.

Other: Ingestion of excessive quantities of magnesium sulfate can cause gastrointestinal effects, kidney injury, and depression of the central nervous system that can lead to death.

☼ *Chronic Health Effects*

The following chronic (long-term) health effects may occur at some time after exposure to magnesium sulfate and can last for months or even years:

Cancer Hazards: According to information presented in the references, magnesium sulfate has not been shown to cause cancer in animals.

Reproductive Hazard: According to information presented in the references, there are no reports of any teratogenic or reproductive effects resulting from exposure to magnesium sulfate.

Other Chronic Effects: Since magnesium sulfate is excreted by the kidneys, persons with kidney function problems may experience systemic toxicity.

🛡 *Recommended Risk-Reduction Measures*

Even though the toxicity of magnesium sulfate is considered to be relatively low, personnel should avoid direct contact with magnesium sulfate. If a less toxic material or compound cannot be substituted for magnesium sulfate, then *engineering controls* are the most effective method of reducing exposures. The best protection is to enclose operations and/or provide local exhaust ventilation at the site of magnesium sulfate

release. While not always operationally feasible, isolating operations can also reduce exposure. Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around magnesium sulfate. No exposure levels have been established for this compound. This does not mean that exposure is without risk. For low or infrequent exposure, an MSHA/NIOSH-approved full facepiece respirator with a high-efficiency particulate air (HEPA) filter may provide adequate protection. A supplied-air respirator operated in continuous flow mode or a self-contained breathing apparatus (SCBA) with full facepiece operated in pressure demand are recommended for the greatest possible respiratory protection. If a full facepiece is not available, then chemical/dust goggles should be worn to protect the eyes. A face shield and protective apron should also be worn. To prevent hand and skin exposures, protective gloves should be used.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with magnesium sulfate.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where magnesium sulfate is used or stored.

Before beginning employment working with magnesium sulfate, and at regular intervals thereafter (e.g., annually), those personnel with frequent or potentially high exposures should be provided the following recommended medical tests:

- Kidney function tests (establish baseline).

If symptoms develop or overexposure is suspected, consider the following additional tests:

- Kidney function tests (compare to baseline).
- Magnesium serum levels.
- Lung function tests.

Any evaluation should include a careful history of past and present symptoms with an examination. Medical tests that simply look for existing damage are not a substitute for controlling exposures. Also, since smoking can cause heart disease as well as lung cancer, emphysema, and other known respiratory problems, smokers exposed to magnesium sulfate may experience symptoms more rapidly than non-smokers under the same conditions of exposure. Prudent risk

management requires careful consideration of *all* factors when exposure symptoms appear in the workplace.

Other methods to reduce exposure include:

- Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not used, respiratory protection should be mandatory.
- Always ensure that proper protective clothing is worn when using chemical substances. Proper maintenance and care of protective equipment is essential to its proper function.
- Wash thoroughly immediately after exposure to magnesium sulfate and at the end of the work shift or before eating, drinking, or smoking.
- Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of magnesium sulfate should be communicated to all exposed and potentially exposed workers.
- Eye wash stations should be provided in the immediate work area for emergency use. If there is a possibility of skin exposure to magnesium sulfate, emergency shower facilities should be provided in the immediate area.
- Workers whose clothing has been contaminated by magnesium sulfate should change into clean clothes before leaving work. Contaminated work clothes should be laundered only by individuals who have been informed of the hazards of exposure to magnesium sulfate.

RISK ASSESSMENT: ENVIRONMENT

General Assessment

As a naturally occurring mineral, magnesium poses very little threat to the environment. However, accidental spills or releases of magnesium sulfate to the environment can occur during transportation, storage, disposal, or destruction of magnesium sulfate. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance. Accidental spills, large or small, where magnesium sulfate contacts incompatible commodities can result in release of toxic products (depending upon conditions of spill), and possible contamination of the surrounding environmental mediums (water, soil, and air).

Magnesium sulfate is considered a non-combustible solid. However, potentially explosive reactions can occur when it is heated in the presence of ethoxyethyl alcohols. It is also incompatible with arsenates, phosphates, and tartrates. It can react with many other metals such as lead, barium, and calcium to precipitate the formation of their respective sulfates. Therefore, extreme caution is required in handling, storage, transportation, and disposal of magnesium sulfate. These characteristics also require special consideration during any emergency situation involving a leak or spill of magnesium sulfate powder or dust. Should magnesium sulfate ever come into contact with these incompatible substances either during use, transportation, storage, or disposal, violent and even explosive reactions are extremely possible.

Magnesium sulfate may enter the environment as a result of industrial and municipal waste treatment plant discharges and from spills.

☠ *Acute Ecological Effects*

Acute (short-term) toxic effects may include the death of animals, birds, or fish and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to magnesium sulfate. Magnesium and its salts have slight acute toxicity to aquatic life. Insufficient data are available to evaluate the short-term effects of magnesium sulfate to plants, birds, or land animals.

🕒 *Chronic Ecological Effects*

Chronic (long-term) toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals. Magnesium and its salts have slight chronic toxicity to aquatic life. Insufficient data are available to evaluate or predict the long-term effects of magnesium sulfate to plants, birds, or land animals.

💧 *Water Solubility*

Magnesium sulfate is highly soluble in water. Concentrations of 1000 milligrams and more will mix with a liter of water.

🕒 *Persistence in the Environment*

Magnesium is highly persistent in water, with a half-life greater than 200 days. The half-life of a pollutant is the amount of time it takes for one half of the

chemical to be degraded. Magnesium is also naturally present in terrestrial soils and aquatic sediments.

🐟 *Bioaccumulation in Aquatic Organisms*

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans.

The concentration of magnesium sulfate found in fish tissues is expected to be about the same as the average concentration of magnesium sulfate in the water from which the fish was taken.

🛡️ *Recommended Risk-Reduction Measures*

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in a leak or spill of magnesium sulfate dusts or powders into the environment. The correct use of labeling on all containers, trucks, and rail cars will enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of magnesium sulfate should be segregated from incompatible chemicals to minimize the risk of cross-contamination or contact. Care should be taken to prevent physical damage to storage containers. Also, dusty conditions must be avoided in storage and use areas.

If a spill or leak to the environment has occurred, fire department, emergency response and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those trained in proper spill containment procedures. Contaminated soils should be removed for decontamination and replaced with clean soil. If magnesium sulfate should contact the water table, aquifer, or navigable waterway, time is of the essence. It is highly soluble and total remediation may not be possible. The local and/or state emergency response authorities may require notification. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of magnesium compounds.

If magnesium sulfate is spilled or leaked, the following specific steps are recommended:

- Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened for normal work.
- Remove all ignition sources from area.

- ☑ Ventilate area of spill or leak.
- ☑ Collect powdered materials in the safest manner possible and deposit in sealed containers. Recommend using a vacuum equipped with a high-efficiency particulate air (HEPA) filter. Do not dry sweep (generates airborne dusts). Damp mop residues and collect for disposal. Water spray can be used to knock down vapors. Runoff should also be collected for disposal.
- ☑ It may be necessary to dispose of magnesium sulfate as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving magnesium sulfate can present a significant threat to business operations. The loss or damage of equipment or facilities can significantly affect fiscal viability. Lawsuits that may result from personnel injury/death, public exposures, and/or environmental contamination will also require a serious expenditure of resources. Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business.

Recommended Risk-Reduction Measures

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures for responding to chemical incidents. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

Special Fire Fighting Procedures

Poisonous gases are produced in fire; wear full protective clothing and self-contained breathing apparatus (SCBA). If possible, fight fire from a distance and avoid smoke (consider down-wind conditions). Move containers from fire area if it can be done safely. Use chlorine bleach solution to decontaminate.

Unusual Fire and Explosion Hazards

Containers may explode when exposed to heat of a fire. Use water spray to cool fire-exposed containers that cannot be moved from fire area. Evacuate non-essential personnel 2000 feet from fire area.

SECTION V - REACTIVITY DATA

| | | |
|---------------------------------|----------------------------|---|
| Stability | | Conditions to Avoid Malathion is kept stable in aqueous solution that has been buffered to pH of 5.25. Avoid contact with incompatible materials. Keep away from heat and flame. |
| Stable X | Unstable | Incompatibility (<i>materials to avoid</i>) Incompatible with strong oxidizers, magnesium, alkaline pesticides, and is corrosive to many metals including steel, tin plate, lead, and copper. It will attack some forms of plastic, rubber, and coatings. |
| Hazardous Polymerization | | Conditions to Avoid Under normal conditions of temperature and pressure, hazardous polymerization of malathion will not occur. |
| May Occur | Will Not Occur X | Hazardous Decomposition or By-products Acrid and irritating gases and fumes are produced when malathion is involved in fire, including sulfur dioxide, phosphoric acid, carbon monoxide, and phosphorus oxides. Decomposition may be explosive. |

SECTION VI - HEALTH HAZARD DATA

| | | | |
|-----------------------------------|-------------------------|--------------------------------|------------------------|
| Primary Route(s) of Entry: | Inhalation? X | Absorption (skin)? X | Ingestion? X |
|-----------------------------------|-------------------------|--------------------------------|------------------------|

Health Hazards

INHALATION: Tightness in chest, wheezing, coughing, bluish discoloration of the skin, small pupils, an aching in and behind the eyes, blurred vision, tearing, runny nose, headache, an increase in pulmonary secretions, and watering in the mouth. CNS effects may include weakness, generalized twitching and paralysis, dizziness, confusion, slurred speech, staggering gait, sweating, irregular heartbeat, convulsions, stopped breathing, coma. Also inhibits blood cholinesterase.

ABSORPTION: Irritation to the skin and eyes. May absorb to cause toxic systemic effects, including sweating and twitching. Mild sensitization and dermatitis may occur at high exposures.

INGESTION: Loss of appetite, nausea, vomiting, abdominal cramps, and diarrhea within 2 hours.

| | | | | |
|---|--------------------------|---|------------------------------|--|
| Carcinogenicity Unknown Human Questioned Animal | NTP Listed? No | IARC Cancer Review Group? Group 3 | OSHA Regulated? No | Target Organs? Resp. sys., liver, eyes, skin, CNS, CVS, blood, GI. |
|---|--------------------------|---|------------------------------|--|

Medical Conditions Generally Aggravated by Exposure

Existing central nervous system disorders may be aggravated by exposure.

Emergency and First-aid Procedures

Eye contact: Flush immediately with water for 15 minutes (minimum); seek medical attention. **Skin contact:** Remove all contaminated clothing. Immediately wash area with large amounts of soap and water. **Seek medical assistance. For inhalation:** Remove the person from exposure. Provide respiratory assistance and CPR. Transfer to medical facility. **If swallowed:** Contact poison control center. Unless advised otherwise, do NOT induce vomiting. Consider gastric lavage *after* control of seizures.

SECTION VII - PRECAUTIONS FOR SAFE HANDLING AND USE

Steps to be Taken in Case Material is Released or Spilled

Absorb liquids in vermiculite or other absorbent and deposit in DOT-approved drum. Ventilate area and remove ignition sources. Restrict those not involved in cleanup from entering area. Do not use plastic or rubber tools during cleanup since malathion can attack such materials.

Preferred Waste Disposal Method

Mix in flammable solvent and burn in chemical incinerator equipped with afterburner and scrubber.

Precautions to be Taken in Handling and Storage

Store in tightly closed containers in a cool, well-ventilated, moisture-free area. Personnel working with malathion should be trained on its hazards *prior* to being assigned to such responsibilities.

Other Precautions and Warnings

Do not store in steel, iron, tin plate, lead, or copper containers. Also keep away from rubber and plastic.

SECTION VIII - CONTROL MEASURES AND PERSONAL PROTECTIVE EQUIPMENT

Respiratory Protection (*specify type*)

For relatively low or infrequent exposure to powders, use a full facepiece respirator equipped with a high-efficiency particulate air (HEPA) filter and dust/mist pre-filter. For greater protection, use a supplied-air respirator with full facepiece operated in pressure demand mode or a self-contained breathing apparatus (SCBA) with full facepiece operated in pressure demand or other positive pressure mode.

Ventilation

Local exhaust or general mechanical systems recommended.

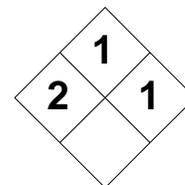

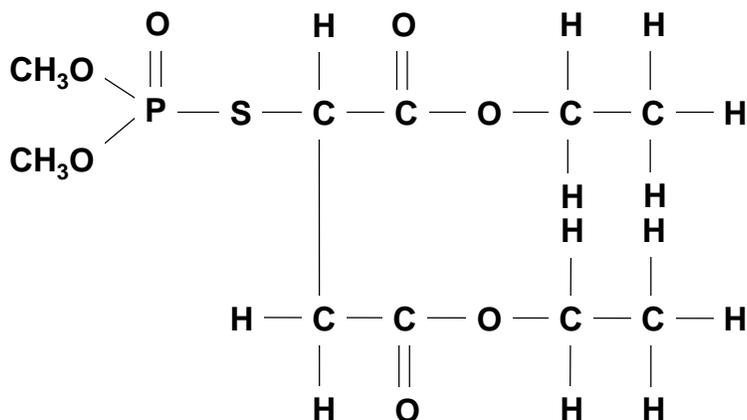

| | | |
|---|---|---|
| Protective Gloves Impervious Material | Eye Protection Chemical/Dust Goggles or Face Mask | Other Protective Clothing Whole Body Protection |
|---|---|---|

Work/Hygiene Practices

Always wash hands thoroughly after using chemical; never bring food, drink, or smoking materials into vicinity of chemicals.

MALATHION

CAS: 121-75-5

**IDENTIFICATION AND TYPICAL USES**

Malathion is a colorless (in pure form) to dark brown to yellow liquid with a garlic or skunk-like odor. It is an insecticide used for control of mosquitoes, the Mediterranean fruit fly, spiders, animal ectoparasites, and human head and body lice or mites.

RISK ASSESSMENT: HEALTH**General Assessment**

Malathion is primarily toxic to humans by *ingestion*. However, its vapors can also cause adverse systemic effects by *inhalation*, and skin contact may result in *absorption* which will also cause adverse systemic effects. Contact with the eyes or skin will result in irritation. It is a questionable carcinogen with human mutation data also reported. It is also an experimental teratogen with positive evidence of reproductive effects in animals.

Inhalation of malathion vapors will cause tightness in the chest, wheezing, increased pulmonary secretions, bluish color in the skin, constricted pupils, an aching feeling in and behind the eyes, blurred vision, lachrymation (tearing), runny nose, headache, and watering mouth. It will cause systemic effects with action on the central nervous system. Action on the central nervous system can include weakness, general twitching and paralysis, dizziness, confusion, staggering gait, slurred speech, sweating, irregular heart-beat, convulsions, stopped breathing, and coma. This compound is also an inhibitor of cholinesterase, an enzyme that is essential to the proper functioning of the muscles.

☠ Acute Health Effects

The following acute (short-term) health effects may occur immediately or shortly after exposure to malathion:

Skin: Irritation and possible inflammation. May absorb through unbroken skin to cause toxic systemic effects, including sweating and twitching at site of absorption.

Eye: Irritation and possible inflammation.

Lung: Irritation of the mucosa of the nose, throat, and upper respiratory tract. Effects are more systemic than localized, with action on the blood, central nervous system, and (possibly) the cardiovascular system.

CNS: A depressant, causing headache, blurred vision, giddiness, nervousness, and other systemic effects.

Other: Ingestion of malathion will result in loss of appetite, nausea, vomiting, abdominal cramps, and diarrhea with 2 hours of exposure.

☘ Chronic Health Effects

The following chronic (long-term) health effects may occur at some time after exposure to malathion and can last for months or even years:

Cancer Hazards: According to the information presented in the references, malathion has been shown to cause cancer in test animals. It has been shown to

cause mutations (genetic changes) in humans and may pose a cancer risk as well.

Reproductive Hazard: According to the information presented in the references, malathion may damage the developing fetus in humans since it has been shown to be fetotoxic in animals.

Other Chronic Effects: Chronic exposure to malathion has not been sufficiently studied. However, there is some indication that long-term exposure or frequent high exposures may inhibit the essential enzyme cholinesterase. It may also cause dermal sensitization as well as dermatitis in some people.

🔑 **Recommended Risk-Reduction Measures**

Malathion is less toxic to humans than most other anticholinesterase agents. However, less toxic substances should always be sought as a first step towards risk reduction. If a less toxic chemical cannot be substituted for a hazardous substance, *engineering controls* are the most effective method of reducing exposures. The best protection is to enclose operations and/or provide local exhaust ventilation at the site of chemical release. While not always operationally feasible, isolating operations can also reduce exposure. These controls certainly may not be practical or applicable when using malathion as an insecticide, especially outdoors. However, during manufacture, transportation, or storage, these engineering controls may be effective in reducing exposure risk.

Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around malathion. The exposure level for this compound is relatively low and may be difficult to measure and even more difficult to protect against. At low or infrequent exposures, a full facepiece respirator equipped with a high-efficiency particulate air (HEPA) filter and a dust/mist pre-filter may suffice. However, for maximum exposure risk reduction or for exposures to high concentrations, a self-contained breathing apparatus (SCBA) with full facepiece operated in pressure demand is the recommended respiratory protection of choice. If a full facepiece is not available, then chemical goggles should be worn to protect the eyes. Whenever a chemical splash hazard exists, a face shield and protective apron should be worn. To prevent hand and skin exposures, impervious gloves should be worn. Caution is warranted in glove selection since malathion will attack rubbers, some plastics, and many coatings. Glove manufacturers should be contacted

and permeation studies obtained *before* final glove selections are made.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with malathion.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where malathion is used or stored.

If symptoms develop or overexposure is suspected, the following medical tests may be useful:

- Complete blood count (CBC).

Any evaluation should include a careful medical history of past and present symptoms with an examination. However, medical tests that evaluate existing damage are not a substitute for controlling exposure.

Other methods to reduce exposure include:

- Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not used, respiratory protection should be mandatory.
- Always ensure that proper protective clothing is worn when using chemical substances.
- Wash thoroughly immediately after exposure to malathion and at the end of the work shift or before eating, drinking, or smoking.
- Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of malathion should be communicated to all exposed workers.
- Eye wash stations should be provided in work areas. If the potential for whole body exposure exists, then safety showers should also be provided.

RISK ASSESSMENT: ENVIRONMENT

General Assessment

The environment is at risk of exposure during the intended use as an insecticide, as well as during transportation, storage, disposal, or destruction of malathion. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance. Accidental spills,

large or small, can result in fire, explosion, and possible contamination of the surrounding environmental mediums (water, soil, and, to a lesser extent, air).

Malathion is considered a Class IIIB combustible liquid (per OSHA 29 CFR 1910.106). These characteristics require special consideration during any emergency situation involving a leak or spill of malathion. Should malathion ever come into contact with incompatible substances such as strong oxidizers, alkaline pesticides, or metals such as magnesium, iron, steel, tin plate, lead, or copper, either during use, transportation, or storage, violent reactions can occur. Malathion will slowly hydrolyze in water to dilute maleic acid.

Malathion can enter the environment through its intended use as an insecticide, through industrial discharges, and from spills.

☠ *Acute Ecological Effects*

Acute (short-term) toxic effects may include the death of animals, birds, or fish and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to malathion.

This chemical has high acute toxicity to aquatic life and moderate acute toxicity to birds. Insufficient data are available to evaluate or predict the short-term effects of malathion to plants or land animals.

🕒 *Chronic Ecological Effects*

Chronic toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals.

Malathion has high chronic toxicity to aquatic life. Insufficient data are available to evaluate or predict the long-term effects of malathion to plants, birds, or land animals.

💧 *Water Solubility*

Malathion is very slightly soluble in water. Concentrations of 1 milligram or less will mix with a liter of water.

🕒 *Persistence in the Environment*

Malathion is slightly persistent in water, with a half-life of between 2 to 20 days. The half-life of a pollutant is the amount of time it takes for one half of the chemical to be degraded.

🐟 *Bioaccumulation in Aquatic Organisms*

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans.

Malathion is not expected to accumulate in the edible tissues of fish normally consumed by humans.

🛡️ *Recommended Risk-Reduction Measures*

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in a leak or spill to the environment. The correct use of DOT labeling (per the MSDS) on all containers, trucks, and rail cars will enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of malathion should be segregated from incompatible chemicals to minimize the risk of cross-contamination or contact. It should be kept in dry areas away from water and moisture.

If a spill or leak to the environment has occurred, fire department, emergency response and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those trained in proper spill containment procedures. Contaminated soils should be removed for incineration and replaced with clean soil. If malathion should contact the water table, aquifer, or navigable waterway, remediation activities should be prompt to ensure protection of aquatic sediments. When such spills occur, the local and/or state emergency response authorities must be notified. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of malathion. If malathion is spilled or leaked, the following specific steps are recommended:

- ☑ Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened for normal work.
- ☑ Ventilate area and remove ignition sources.
- ☑ Absorb liquid spills using vermiculite, dry earth, or sand and place in a sealed drum for disposal. Avoid using plastic or rubber tools during cleanup since malathion can attack such materials.

- ☑ It may be necessary to dispose of malathion as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving malathion can present a significant threat to business operations. The loss or damage of equipment or facilities can significantly affect fiscal viability. Lawsuits that may result from personnel injury/death, public exposures, and/or environmental contamination will also require a serious expenditure of resources. Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business. Always remember that anytime the terms "cancer," "carcinogen," or "reproductive hazard" are used, public emotion, hysteria, and ignorance can run equally high. This should be carefully considered whenever developing or implementing public relations policies.

Recommended Risk-Reduction Measures

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures dealing with safety or emergency response. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

MALEIC ACID

CAS: 110-16-7

**IDENTIFICATION AND TYPICAL USES**

Maleic acid appears as a white crystalline solid with a faint acidulous odor and a repulsive, astringent, characteristic taste. It is used in organic synthesis of severe acids (malic, succinic, aspartic, tartaric, propionic, lactic, malonic, and acrylic). It is also used in the textile industry for dyeing and finishing of cotton, wool, and silk. It is a preservative for oils and fats.

RISK ASSESSMENT: HEALTH**General Assessment**

Exposure to maleic acid is possible through *inhalation* of its dusts or mists and possibly by *ingestion*, although the latter is not considered a likely exposure route. The data in the references are limited regarding its specific toxicity. However, there are no reports of animal or human carcinogenicity, mutagenicity, or teratogenicity.

Inhalation of maleic acid dusts or mists will cause severe irritation of the eyes, nose, throat, and mucous membranes of the upper respiratory tract. Because of its acidic nature, bronchial tube irritation with coughing and phlegm may also occur.

Skin and eye contact with concentrated solutions can result in mild to moderate irritation. On the skin, maleic acid can cause burns and irritation, especially if the skin is moist (sweat). Repeated contact or high exposures may cause dermatitis. If allowed to remain in contact with the eye for prolonged periods, corneal edema, burns, and conjunctivitis may occur.

☠ Acute Health Effects

The following acute (short-term) health effects may occur immediately or shortly after exposure to maleic acid:

Skin: Irritation/rash or burning feeling on contact, with possible development of dermatitis.

Eye: Severe irritation; may cause burns, conjunctivitis, and corneal damage.

Lung: Irritation of the nose, throat, and mucosa of the lungs and respiratory tract. Because of the acidic nature, bronchial tube irritation with cough and phlegm may occur.

☼ Chronic Health Effects

The following chronic (long-term) health effects may occur at some time after exposure to maleic acid and can last for months or even years:

Cancer Hazards: According to information presented in the references, maleic acid has not been adequately tested for its ability to cause cancer in animals. Additional research is required.

Reproductive Hazard: According to information presented in the references, maleic acid has not been adequately tested for its ability to adversely affect reproduction in laboratory animals.

🛡 Recommended Risk-Reduction Measures

Personnel should avoid direct contact with maleic acid. The exact nature of its toxicity is not clearly understood in the references. If a less toxic chemical cannot be substituted for a hazardous substance, then *engineering controls* are the most effective method of reducing exposures.

The best protection is to enclose operations and/or provide local exhaust ventilation at the site of chemical release. While not always operationally feasible, isolating operations can also reduce exposure. Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever

working with or around maleic acid. No exposure levels have been established for maleic acid. This does not mean that exposure is without health risk. Prudent risk management may require a conservative approach to respiratory protection until further data are known about maleic acid. For transient exposures, an air-purifying respirator equipped with an acid cartridge, a high-efficiency particulate air (HEPA) filter, and a dust/mist pre-filter may suffice. Greater protection is obtained using a supplied-air respirator or a self-contained breathing apparatus (SCBA) with full facepiece operated in pressure demand or other positive pressure mode. If a full facepiece is not available, then chemical goggles should be worn to protect the eyes. Whenever a chemical splash/dust hazard exists, a face shield and a rubber apron should be worn. To prevent hand and skin exposures, acid resistant gloves should be worn. Glove manufacturers should be contacted and permeation studies obtained *before* final glove selections have been made.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with maleic acid.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where maleic acid is used or stored. Other methods to reduce exposure include:

- ☑ Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not used, then the use of respiratory protection should be mandatory.
- ☑ Always ensure that proper protective clothing is worn when using chemical substances and that personnel are trained in its use and care.
- ☑ Wash thoroughly immediately after exposure to maleic acid and at the end of the work shift or before eating, drinking, or smoking.
- ☑ Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of maleic acid should be communicated to all exposed or potentially exposed workers.

RISK ASSESSMENT: ENVIRONMENT

General Assessment

The environment is at risk of exposure during transportation, storage, disposal, or destruction of maleic acid. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance. Accidental spills, large or small, can result in fire, explosion, and possible contamination of the surrounding environmental mediums (water, soil, and air).

Maleic acid is considered a non-combustible solid. It may be corrosive, especially when mixed in solution. It is incompatible with oxidizers such as chlorine or fluorine and contact can cause a violent reaction. It may corrode metals when wet. These characteristics require special consideration during any emergency situation involving a leak or spill of maleic acid.

Maleic acid can enter the environment mainly in industrial discharges or spills.

☠ Acute Ecological Effects

Acute (short-term) toxic effects may include the death of animals, birds, or fish and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to maleic acid.

Maleic acid has moderate acute toxicity to aquatic life. Insufficient data are available to evaluate or predict the short-term effects of maleic acid exposure to birds, plants, or land animals.

☪ Chronic Ecological Effects

Chronic (long-term) toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals. Insufficient data are available to evaluate or predict the long-term effects of maleic acid exposure to aquatic life, birds, plants, or land animals.

💧 Water Solubility

Maleic acid is slightly soluble in water. Concentrations of 1 milligram will mix with a liter of water.

🕒 Persistence in the Environment

Maleic acid is moderately persistent in the aquatic environment, with a half-life of between 2 to 20 days. The half-life of a pollutant is the amount of time it takes for one half of the chemical to be degraded.

🌊 Bioaccumulation in Aquatic Organisms

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans.

Maleic acid can be expected to biodegrade quickly and should not accumulate in the edible tissues of fish.

🕒 **Recommended Risk-Reduction Measures**

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in a leak or spill to the environment. The correct use of DOT labeling on all containers, trucks, and rail cars will enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of maleic acid should be segregated from incompatible chemicals to minimize the risk of cross-contamination or contact. Buildings designated for storage should be equipped with appropriate fire protection systems (alarms, sprinklers, emergency lighting, portable extinguishers).

If a spill or leak to the environment has occurred, fire department, emergency response and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those trained in proper spill containment procedures. Contaminated soils should be removed for incineration and replaced with clean soil. If maleic acid should contact the water table, aquifer, or navigable waterway, time is of the essence. It is miscible in water and, therefore, total containment and remediation may not be possible. When such spills occur, the local and/or state emergency response authorities must be notified. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of maleic acid. If maleic acid is spilled or leaked, the following specific steps are recommended:

- ☑ Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened for normal work.
- ☑ Remove ignition sources and ventilate area.
- ☑ Collect all powdered materials in safest and most convenient manner possible and deposit in sealed drums for disposal. Do NOT dry sweep (generates airborne dusts). Use a vacuum equipped with a high efficiency particulate air

(HEPA) filter instead. Damp mop residue and collect for disposal. Absorb any solution spills in vermiculite, dry sand, earth, or similar material and deposit in sealed containers.

- ☑ It may be necessary to dispose of maleic acid as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving maleic acid can present a significant threat to business operations. The loss or damage of equipment or facilities can significantly affect fiscal viability. Lawsuits that may result from personnel injury/death, public exposures, and/or environmental contamination will also require a serious expenditure of resources. Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business.

🕒 **Recommended Risk-Reduction Measures**

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures dealing with safety or emergency response. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

MATERIAL SAFETY DATA SHEET

CHEMICAL NAME

MALEIC ANHYDRIDE

CRC PRESS/LEWIS PUBLISHERS DISCLAIMER: THE INFORMATION AND RECOMMENDATIONS PRESENTED HEREIN ARE BASED ON SOURCES BELIEVED TO BE RELIABLE. CRC MAKES NO REPRESENTATION ON ITS COMPLETENESS OR ACCURACY. IT IS THE RESPONSIBILITY OF THE USER TO DETERMINE THE CHEMICAL'S SUITABILITY FOR ITS INTENDED USE, THE CHEMICAL'S SAFE USE, AND THE CHEMICAL'S PROPER DISPOSAL. NO REPRESENTATIONS AND/OR WARRANTIES, EITHER EXPRESSED OR IMPLIED, OF THE MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE, OR OF ANY OTHER NATURE, ARE MADE WITH RESPECT TO THE INFORMATION PROVIDED IN THIS MSDS OR TO THE CHEMICAL TO WHICH INFORMATION MAY REFER. CRC NEITHER ASSUMES NOR AUTHORIZES ANY OTHER PERSON TO ASSUME FOR IT, ANY OTHER ADDITIONAL RESPONSIBILITY OR LIABILITY FOR THE USE OF, OR RELIANCE UPON, THIS INFORMATION.

HAZARD WARNING INFORMATION

| HEALTH | FIRE | REACTIVE | OTHER | DEGREE OF HAZARD | COLOR CODING | OTHER CODES |
|----------|----------|----------|-------|---|---|---|
| 3 | 1 | 1 | | 0 = Minimum Hazard 1 = Slight Hazard 2 = Moderate Hazard 3 = Serious Hazard 4 = Severe Hazard | HEALTH = BLUE FIRE = RED REACTIVITY = YELLOW OTHER = WHITE | OX = Oxidizer ACID = Acid ALK = Alkali COR = Corrosive W = Use No Water |

SECTION I - GENERAL INFORMATION

| | | |
|---|--|---------------------------------|
| Characterization Anhydride | RCRA Number U147 | EPA Class Toxic Waste |
| DOT Proper Shipping Name Maleic anhydride | Chemical Abstract Service (CAS) Number 108-31-6 | |
| DOT Hazard Class and Label Requirements ORM-A | DOT Emergency Guide Code 60 | |
| DOT Identification Number UN 2215 | Chemical Formula C₄H₂O₃ | |

Synonyms

cis-Butenedioic anhydride; 2,5-dihydrofuran-2,5-dione; 2,5-furandione; toxilic anhydride.

SECTION II - HAZARDOUS INGREDIENTS AND IDENTITY INFORMATION

| Hazardous Components (specific identity) | OSHA Exposure Criteria | NIOSH Exposure Criteria | Immediately Dangerous to Life and Health (IDLH) | ACGIH Exposure Criteria |
|--|--|--|---|--|
| Maleic anhydride (derivation: By catalytic vapor-phase oxidation of benzene or other hydrocarbons). 1 ppm = 4.08 mg/m³ | PEL (8-hour): 0.25 ppm 1.0 mg/m³ STEL: Not Established | REL (10-hour): 0.25ppm 1.0 mg/m³ STEL: Not Established | 10 mg/m³ | TLV: 0.25ppm 1.0 mg/m³ STEL: Not Established |

SECTION III - PHYSICAL AND CHEMICAL CHARACTERISTICS

| | |
|--|--|
| Boiling Point 396°F (202°C) | Specific Gravity (H ₂ O = 1) 1.48 |
| Vapor Pressure (mm Hg) 0.16 at 69°F (20°C) | Molecular Weight 98.1 |
| Vapor Density (Air = 1) 3.4 | Melting Point 127°F (53°C) |

Solubility

Soluble in water (forms maleic acid). Soluble in dioxane, very slightly soluble in alcohol.

Appearance and Odor

Odorless, colorless, needles or crystals, white lumps, or pellets with an irritating, choking odor. Odor Threshold = .4 ppm. May be shipped in molten form.

SECTION IV - FIRE AND EXPLOSION HAZARD DATA

| | |
|---|--|
| Flash Point (method used) 218°F (103°C) | Explosive Limits in Air % by Volume LEL: 1.4% UEL: 7.1% |
| NFPA Classification Combustible Solid | Autoignition Temperature 891°F (477°C) |

Extinguishing Media

Use alcohol foam or carbon dioxide. Do NOT use dry chemical (exothermic reaction).

Special Fire Fighting Procedures

Poisonous gases are produced in fire; wear full protective clothing and self-contained breathing apparatus (SCBA). Isolate area and deny entry to those not involved in response procedures. Move containers from fire area if it can be done without risk. If this is not possible, use water spray to keep fire-exposed containers cool. Do NOT release runoff from fire control measures to sewers or waterways.

Unusual Fire and Explosion Hazards

Reacts with water to form corrosive maleic acid. Maleic anhydride in the form of vapor, cloud, or mist may ignite spontaneously in air and may re-ignite after fire has been extinguished.

SECTION V - REACTIVITY DATA

| | | |
|---------------------------------|----------------|--|
| Stability | | Conditions to Avoid Extremely volatile solid but kept stable if containers are properly vented. Avoid contact with water and moisture, and keep away from heat and ignition sources. |
| Stable X | Unstable | Incompatibility (<i>materials to avoid</i>) Strong oxidizers (chlorine), water. Alkali, alkaline earth, metal ions, ammonium ions, caustics, amines (at temperatures above 150°F). |
| Hazardous Polymerization | | Conditions to Avoid Maleic anhydride does not self-polymerize. However, it can undergo uncontrolled co-polymerization when mixed with olefins and catalysts. Explosive decomposition can occur in the presence of alkalis. |
| May Occur X | Will Not Occur | Hazardous Decomposition or By-products When heated to decomposition, maleic anhydride emits toxic and irritating fumes and vapors and carbon monoxide. |

SECTION VI - HEALTH HAZARD DATA

| | | | |
|-----------------------------------|-------------------------|--------------------|------------------------|
| Primary Route(s) of Entry: | Inhalation? X | Absorption (skin)? | Ingestion? X |
|-----------------------------------|-------------------------|--------------------|------------------------|

Health Hazards

INHALATION: Causes irritation of the eyes, nose, throat, and respiratory system with coughing, sneezing, dyspnea, mucous membrane irritation in the nasal cavity leading to ulceration of the septum, chemical bronchitis, or delayed pulmonary edema. Nervous system effects also possible, including mental confusion, nausea, muscular twitching, and blurred vision.

SKIN & EYES: Skin contact causes serious caustic burns, itchy rash, and dermatitis. Eye contact may cause burns, irritation, corneal scarring, and perhaps permanent damage.

INGESTION: Burning of the mouth, esophagus, and digestive tract. Pain in the chest, stomach, and painful swallowing.

| | | | | |
|--|--------------------------|--|--|--|
| Carcinogenicity Unknown Human Unknown Animal | NTP Listed? No | IARC Cancer Review Group? No | OSHA Regulated? 29 CFR 1910.1000 Table Z-1 | Target Organs? Skin, eyes, respiratory system. |
|--|--------------------------|--|--|--|

Medical Conditions Generally Aggravated by Exposure

Existing chronic respiratory diseases may be aggravated by exposure.

Emergency and First-aid Procedures

Eye contact: Flush immediately with water for 15 minutes (minimum); seek medical attention. **Skin contact:** Remove all contaminated clothing. Wash area with large amounts of soap and water. Seek medical assistance. For **inhalation:** Remove the person from exposure. Provide respiratory assistance and CPR. Transfer to medical facility. Observe 48 hours for lung effects. If **swallowed:** Contact poison control center. Unless told otherwise, give 1-2 glasses of water to dilute then induce vomiting. Save some of the vomitus for analysis. After the vomiting, have the person drink 2 tablespoons of activated charcoal in 8 oz. of water. Never give an unconscious or convulsing person anything by mouth.

SECTION VII - PRECAUTIONS FOR SAFE HANDLING AND USE

Steps to be Taken in Case Material is Released or Spilled

Collect powdered material using a vacuum equipped with HEPA filter; deposit in sealed drums for disposal. Avoid skin contact. Do NOT dry sweep (generates dusts). Allow molten materials to solidify, then treat as a solid. Absorb liquids in vermiculite and collect for disposal. Keep water away. Ventilate area.

Preferred Waste Disposal Method

No citation.

Precautions to be Taken in Handling and Storage

Do not store maleic anhydride in the presence of incompatible chemicals or materials. Store in tightly closed containers in a cool, dark, well-ventilated area. Personnel working with maleic anhydride should be trained on its proper handling and storage prior to being assigned to such responsibilities.

Other Precautions and Warnings

Keep away from water and incompatible materials.

SECTION VIII - CONTROL MEASURES AND PERSONAL PROTECTIVE EQUIPMENT

Respiratory Protection (*specify type*)

PEL is extremely low (0.25 ppm). Use a self-contained breathing apparatus (SCBA) with full facepiece or a supplied-air respirator operated in pressure demand or other positive pressure mode.

Ventilation

Local exhaust or general mechanical systems recommended.

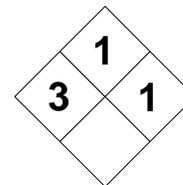

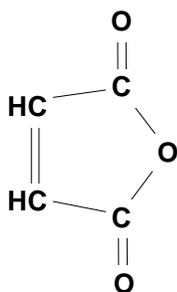

| | | |
|---|---|--|
| Protective Gloves Impervious Material | Eye Protection Chemical/Dust Goggles or Face Mask | Other Protective Clothing Protective Apron |
|---|---|--|

Work/Hygiene Practices

Always wash hands thoroughly after using chemical; never bring food, drink, or smoking materials into vicinity of chemicals.

MALEIC ANHYDRIDE

CAS: 108-31-6

**IDENTIFICATION AND TYPICAL USES**

Maleic anhydride appears as colorless needles or crystals, white lumps, pellets, briquettes, rods, or flakes with an acrid, irritating, choking odor. It is often shipped in molten form. It is used primarily in the manufacture of polyester resins, in alkyd coating resins, in fumaric and tartaric acid, in pesticides, as a preservative in oils and fats, and in permanent-press (textiles).

RISK ASSESSMENT: HEALTH**General Assessment**

Maleic anhydride is a human poison primarily by *inhalation*, causing toxic systemic effects targeting the respiratory system. It can also cause toxic effects by *ingestion*. It is a questionable carcinogen with human mutation data reported. There are no reports of its teratogenic effects in humans or animals.

Inhalation of maleic anhydride dusts can be irritating to the nose, throat, mucosa, and the upper respiratory tract. Asthmatic-like symptoms include coughing, sneezing, dyspnea, ulceration of the nasal septa, chemical bronchitis, and the possibility of pulmonary edema (a dangerous buildup of fluid in the lungs). Pulmonary edema can be delayed up to 48 hours or more, thereby creating a false sense of security with regard to health exposure risk. There can be severe headache, nose bleeds, nausea, and temporary vision impairment (photophobia, double vision, blurred vision). There can also be effects subsequent to depression of the central nervous system. These effects can include headache, nausea, dizziness, drowsiness, lightheadedness, muscular twitching, tremors, mental confusion, coma, and, in severe cases, death.

Ingestion of maleic anhydride can cause burning of the mouth, esophagus, and gastrointestinal tract

with deep, burning pain in the chest and stomach and pain on swallowing.

Skin contact can cause blistering, dermatitis, inflammation, and thermal burns. Sensitization can also occur in some individuals.

☠ Acute Health Effects

The following acute (short-term) health effects may occur immediately or shortly after exposure to maleic anhydride:

Skin: Irritation and possible rash. Moisture on skin's surface will enhance the reaction.

Eye: Severe burns, corneal scarring, and possible damage to vision.

Lung: Severe irritation of the nose, throat, and esophagus. Nasal cavity irritation can lead to ulceration of the septa. Delayed pulmonary edema is possible.

CNS: Dizziness, headaches, nausea, vomiting, muscle spasms, tremor, fatigue, convulsions, dyspnea, nervousness, drowsiness, loss of coordination, coma, and even death.

☘ Chronic Health Effects

The following chronic (long-term) health effects may occur at some time after exposure to maleic anhydride and can last for months or even years:

Cancer Hazards: According to the information presented in the references, maleic anhydride has been shown to cause cancer in test animals. Human mutation data have also been reported.

Reproductive Hazard: According to the information presented in the references, maleic anhydride has not been adequately tested for its ability to adversely affect reproduction.

Other Chronic Effects: Prolonged contact with maleic anhydride can lead to the development of bronchitis and asthma-like symptoms. Dermal and respiratory sensitization are also possible.

🕒 **Recommended Risk-Reduction Measures**

Personnel should avoid direct contact with maleic anhydride. It is a toxic, human poison on inhalation. Its human carcinogenic properties are not clearly understood in the references. If a less toxic chemical cannot be substituted for a hazardous substance, *engineering controls* are the most effective method of reducing exposures. The best protection is to enclose operations and/or provide local exhaust ventilation at the site of chemical release. While not always operationally feasible, isolating operations can also reduce exposure.

Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around maleic anhydride. This chemical has an extremely low permissible exposure limit (0.25 ppm) that is difficult to accurately monitor. Therefore, prudent risk management requires a conservative approach to personal protection. While a chemical respirator with a dust/mist pre-filter may suffice, the best protection is obtained using a supplied-air respirator operated in continuous flow mode or a self-contained breathing apparatus (SCBA) with full facepiece operated in pressure demand or positive pressure mode. If a full facepiece is not available, then chemical/dust goggles should be worn to protect the eyes. Whenever maleic anhydride is being mixed with liquids, a chemical splash hazard exists and a face shield and rubber apron should be worn. To prevent hand and skin exposures, protective gloves should be used. Glove manufacturers should be contacted and permeation studies obtained *before* final glove selections have been made.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with maleic anhydride.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where maleic anhydride is used or stored.

If symptoms develop or overexposure is suspected, the following medical tests may be useful:

- ☑ Lung function tests.
- ☑ Consider chest X-ray after an acute overexposure to maleic anhydride (may be negative if taken immediately following exposure due to delayed development of pulmonary edema).
- ☑ Evaluation by a qualified allergist with careful consideration of exposure history and special testing (may help diagnose skin allergy).

Any evaluation should include a careful medical history of past and present symptoms with an examination. However, medical tests that evaluate existing damage are not a substitute for controlling exposure. Also, since smoking can cause heart disease, emphysema, lung cancer, and other respiratory diseases, smokers may experience symptoms more rapidly than non-smokers under the same conditions of exposure. Prudent risk management requires proper consideration of *all* possible factors that may be causing the appearance of exposure symptoms in the workplace.

Other methods to reduce exposure include:

- ☑ Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not used, then respiratory protection should be mandatory and its use enforced.
- ☑ Always ensure that proper protective clothing is worn when using chemical substances and that personnel are trained in its use, care, and maintenance.
- ☑ Wash thoroughly immediately after exposure to maleic anhydride and at the end of the work shift or before eating, drinking, or smoking.
- ☑ Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of maleic anhydride should be communicated to all exposed or potentially exposed workers.
- ☑ Eye wash stations should be provided in work areas. If the potential for whole body exposure exists, then safety showers should also be provided in the immediate work area.

RISK ASSESSMENT: ENVIRONMENT

General Assessment

The environment is at risk of exposure during transportation, storage, disposal, or destruction of maleic anhydride. In almost every scenario, the threat of en-

environmental exposure is contingent upon the proper handling of the chemical substance. Accidental spills, large or small, can result in fire, explosion, and possible contamination of the surrounding environmental mediums (water, soil, and air).

Maleic anhydride is considered a combustible solid. It can react exothermically with water or moisture to produce maleic acid which is corrosive to most metals. Maleic anhydride mist, dust, or vapor can explode in mixtures with air in contact with an ignition source. These characteristics require special consideration during any emergency situation involving a leak or spill of maleic anhydride or maleic anhydride mixtures. Should maleic anhydride ever come into contact with other incompatible substances, such as strong oxidizers, alkalis, caustics, or heated amines, either during use, transportation, or storage, violent and even explosive reactions can occur. Maleic anhydride can enter the environment from industrial discharges and spills.

☠ *Acute Ecological Effects*

Acute (short-term) toxic effects may include the death of animals, birds, or fish and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to maleic anhydride.

Maleic anhydride has slight acute toxicity to aquatic life. It has caused bud-kill in tung trees (an agricultural crop). Insufficient data are available to evaluate or predict the short-term effects of maleic anhydride to birds or land animals.

🌱 *Chronic Ecological Effects*

Chronic toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals. Insufficient data are available to evaluate or predict the long-term effects of maleic anhydride to aquatic life, plants, birds, or land animals.

💧 *Water Solubility*

Maleic anhydride is only slightly soluble in cold (86°F/30°C) water. It reacts to form maleic acid which is corrosive.

🕒 *Persistence in the Environment*

Maleic anhydride is non-persistent in water, with a half-life of less than 2 days. The half-life of a pollut-

ant is the amount of time it takes for one half of the chemical to be degraded.

🐟 *Bioaccumulation in Aquatic Organisms*

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans.

Maleic anhydride is not expected to accumulate in the edible tissues of fish normally consumed by humans.

🛡️ *Recommended Risk-Reduction Measures*

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in a leak or spill to the environment. The correct use of DOT labeling (per the MSDS) on all containers, trucks, and rail cars will enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of maleic anhydride should be segregated from incompatible chemicals to minimize the risk of cross-contamination or contact. Precautions must be taken to ensure all contact with water or moisture is prevented in use or storage.

If a spill or leak to the environment has occurred, fire department, emergency response and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those trained in proper spill containment procedures. Contaminated soils should be removed for incineration and replaced with clean soil. If maleic anhydride should contact the water table, aquifer, or navigable waterway, remediation activities should be prompt. When such spills occur, the local and/or state emergency response authorities must be notified. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of maleic anhydride. If maleic anhydride is spilled or leaked, the following specific steps are recommended:

- ☑ Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened to normal work.
- ☑ Collect powdered material in the most convenient (safe) manner possible and deposit in sealed containers. Do NOT dry sweep (generates air-

borne dusts). Use a vacuum equipped with a HEPA filter instead. If liquid solutions are spilled, use vermiculite to absorb and place in a sealed drum.

- ☑ It may be necessary to dispose of maleic anhydride as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving maleic anhydride can present a significant threat to business operations. The loss or damage of equipment or facilities can significantly affect fiscal viability. Lawsuits that may result from personnel injury/death, public exposures, and/or environmental contamination will also require a serious expenditure of resources. Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business. Always remember that anytime the terms "cancer" or "carcinogen" are used, public hysteria, emotion, and ignorance can run equally high. This should be carefully considered when developing or implementing any public relations policies.

Recommended Risk-Reduction Measures

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures dealing with safety or emergency response. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

The fumes can lead to metal fume fever with symptoms of fever, chills, nausea, weakness, headache, blurred vision, back stiffness and pain, muscle pain, shallow respiration, dryness in mouth and throat, intense thirst, dry cough, metallic taste, chest tightness, and Mn pneumonitis. It can also lead to degenerative brain effects with symptoms similar to Parkinson's disease. EYES & SKIN: Causes skin and eye irritation. There can be dermatitis, conjunctivitis, corneal damage. INGESTION: Large doses can cause gastrointestinal irritation and other unspecified effects. | | | | |
| Carcinogenicity Unknown Human Questioned Animal | NTP Listed? No | IARC Cancer Review Group? No | OSHA Regulated? No | Target Organs? Respiratory system, eyes, skin, CNS, kidneys, blood. |
| Medical Conditions Generally Aggravated by Exposure Existing kidney dysfunction, brain, or muscle problems may be aggravated by exposure. | | | | |
| Emergency and First-aid Procedures Eye contact: Do not allow victim to keep eyes tightly shut. Flush immediately with water for 15 minutes (minimum); seek medical attention. Skin contact: Remove all contaminated clothing. Immediately wash area with flooding amounts of water. For reddened or blistered skin, seek medical assistance. For <u>inhalation</u>: Remove the person from exposure. Provide respiratory assistance and CPR. Transfer to medical facility. If <u>swallowed</u>: Seek medical attention. Rinse mouth with water. Give 1 to 2 glasses of water and induce vomiting until vomit is clear. Never give anything by mouth to a convulsing person. | | | | |
| SECTION VII - PRECAUTIONS FOR SAFE HANDLING AND USE | | | | |
| Steps to be Taken in Case Material is Released or Spilled Collect powdered materials in most convenient and safe manner and deposit in clean, dry, sealed, metal containers. Dry sweep not recommended. Use HEPA vacuum. Ventilate area of spill. Restrict those not involved in cleanup from entering area. | | | | |
| Preferred Waste Disposal Method Reclaim scrap. | | | | |
| Precautions to be Taken in Handling and Storage Store to avoid contact with incompatible materials. Prevent physical damage to containers. Keep containers tightly closed. Keep moisture and sources of heat away. Use non-sparking tools. | | | | |
| Other Precautions and Warnings Avoid excessive dust generation in storage and handling areas. Personnel should be trained on the proper precautions for working with manganese compounds <i>before</i> initial assignment. | | | | |
| SECTION VIII - CONTROL MEASURES AND PERSONAL PROTECTIVE EQUIPMENT | | | | |
| Respiratory Protection (<i>specify type</i>) For dust exposures, use a respirator with a HEPA filter; otherwise, use a supplied-air respirator or a self-contained breathing apparatus with full facepiece operated in positive pressure mode. | | | | |
| Ventilation Local exhaust (preferred) at site of chemical work or general ventilation. | | | | |
| Protective Gloves Impervious Material | Eye Protection Chemical/Dust Goggles or Face Mask | Other Protective Clothing Protective Apron, Boots | | |
| Work/Hygiene Practices Always wash hands thoroughly after using chemical; never bring food, drink, or smoking materials into vicinity of chemicals. | | | | |

MANGANESE

Mn

CAS: 7439-96-5

**IDENTIFICATION AND TYPICAL USES**

Manganese appears as a silvery-white or reddish gray, brittle, solid or powder with no odor. It is metallic element of atomic number 25, group VIIB of the periodic table, atomic weight 64.9380, and valance of 2, 3, 4, 6, 7 and no stable isotopes. Pure manganese cannot be fabricated. It is used in the manufacture of steel (ferroalloys) as well as for improving corrosion resistance and hardness. It is a high-purity salt for various chemical uses, is used as a purifying and scavenging agent in metal production, and in the manufacture of aluminum by the Toth process.

RISK ASSESSMENT: HEALTH**General Assessment**

Even though manganese is an essential mineral in human nutrition, it can also be toxic by *inhalation* of its fumes and/or by *ingestion* of the powders and dusts. While it has been shown to cause tumors in experimental test animals with mutation data also reported, the exact nature of its human carcinogenic properties is unknown.

Inhalation of manganese fumes can cause acute or chronic poisoning with primary effects on the immune system characterized by symptoms of metal fume fever. These can include fever, chills, general weakness, body aches, frontal headache, blurred vision, back pain and stiffness, muscular cramps, shallow and labored respiration, dryness in the mouth and throat with intense thirst, dry cough, metallic taste, and tightness in the chest occurring several hours after exposure. Lung irritation can become severe with inflammation causing manganese pneumonitis. Other effects of central nervous system depression include headache, insomnia, changes in personality, emotions, and attitude, irritability, inappropriate laughter or crying, hallucinations, effects on vision (double vision, blurred vision), uncontrolled impulse behavior, euphoria, excessive salivation, trembling, staggering

gait, and signs and symptoms normally associated with Parkinson's disease.

☠ Acute Health Effects

The following acute (short-term) health effects may occur immediately or shortly after human exposure to manganese:

Skin: A skin irritant that can cause dermatitis in some individuals.

Eye: Irritation to the eye and associated tissues. It can cause conjunctivitis and corneal damage.

Lung: Irritation of the mucosa of the eyes, nose, throat, and respiratory tract.

CNS: Breathing heated fumes can cause metal fume fever with specific action on the central nervous system.

☘ Chronic Health Effects

The following chronic (long-term) health effects may occur at some time after exposure to manganese and can last for months or even years:

Cancer Hazards: According to the references, manganese has been shown to cause tumors in test animals. Its human carcinogenic potential is unknown. Mutation data have been reported.

Reproductive Hazard: According to the references, there is some limited evidence that chronic overexposure to manganese may cause impotence in human males.

Other Chronic Effects: Prolonged or repeated exposure can damage the central nervous system and cause impaired mental function and degenerative brain changes with personality disorders and physical changes in motor control, vision, and other body functions. Chronic exposure may cause dermatitis.

🛡 Recommended Risk-Reduction Measures

While manganese is an essential mineral in human nutrition, it can be extremely toxic under certain exposure conditions and personnel should, therefore, avoid direct occupational contact with manganese. If a less toxic material or compound cannot be substituted for manganese, then *engineering controls* are the most effective method of reducing exposures. The best protection is to enclose operations and/or provide local exhaust ventilation at the site of manganese dust release. While not always operationally feasible, isolating operations can also reduce exposure. Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around manganese. The exposure ceiling for manganese is relatively low ($5\text{mg}/\text{m}^3$) and difficult to accurately monitor. For low or transient exposures, a chemical cartridge respirator equipped with a high-efficiency particulate air (HEPA) filter and a dust/mist pre-filter may provide adequate respiratory protection. Better protection is obtained using a supplied-air respirator operated in continuous flow mode or a self-contained breathing apparatus (SCBA) with full facepiece operated in pressure demand. If a full facepiece is not available, then chemical/dust goggles should be worn to protect the eyes. A face shield and protective apron should also be worn. To prevent hand and skin exposures, gloves should be used. Glove manufacturers should be contacted *before* selections are made.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with manganese.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where manganese is used or stored.

Before beginning employment working with manganese, and at regular intervals thereafter (e.g., annually), those personnel with frequent or potentially high exposures should be provided the following recommended medical tests:

- Kidney function tests (establish baseline).
- Complete blood count (establish baseline).

If symptoms develop or overexposure is suspected, consider the following additional tests:

- Kidney function tests (compare to baseline).
- Complete blood count (compare to baseline).

- Neurological examination.
- Lung function tests.

Any evaluation should include a careful history of past and present symptoms with an examination. Medical tests that simply look for existing damage are not a substitute for controlling exposures.

Other methods to reduce exposure include:

- Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not used, respiratory protection should be mandatory.
- Always ensure that proper protective clothing is worn when using chemical substances. Proper maintenance and care of protective equipment is essential to its proper function.
- Wash thoroughly immediately after exposure to manganese and at the end of the work shift or before eating, drinking, or smoking.
- Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of manganese should be communicated to all exposed and potentially exposed workers.
- Eye wash stations should be provided in the immediate work area for emergency use. If there is a possibility of skin exposure to manganese, emergency shower facilities should be provided.
- Workers whose clothing has been contaminated by manganese should change into clean clothes before leaving work. Never wear contaminated clothing home where family members can be exposed. Contaminated work clothing should be laundered only by individuals who have been informed of the hazards of exposure to manganese.

RISK ASSESSMENT: ENVIRONMENT

General Assessment

As a naturally occurring mineral, manganese poses very little threat to the environment. However, accidental spills or releases to the environment can occur during transportation, storage, disposal, or destruction of manganese. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance. Accidental spills, large or small, where manganese contacts incompatible commodities can result in release of toxic products

(depending upon conditions of spill), and possible contamination of the surrounding environmental mediums (water, soil, and air).

Manganese is considered a combustible solid. Finely divided dusts and powders may create an explosive mixture in air, in contact with moisture, oxidizing materials, or in contact with an ignition source. Mixtures of manganese dust and aluminum dusts (not an improbable combination) can explode in contact with air. It reacts with water and moisture to evolve explosive hydrogen gas. It is also incompatible with many other materials, including nitrogen dioxide, nitric acid, phosphorus, and nitryl fluoride. Extreme caution is always required in handling, storage, transportation, and disposal of manganese. These characteristics also require special consideration during any emergency situation involving a leak or spill of manganese powder or dust. Should manganese ever come into contact with these various incompatible substances either during use, transportation, storage, or disposal, violent and even explosive reactions are possible.

Manganese occurs naturally in the environment (terrestrial soils and aquatic sediments) and may enter the environment as a result of industrial and municipal waste treatment plant discharges and from spills.

☠ *Acute Ecological Effects*

Acute (short-term) toxic effects may include the death of animals, birds, or fish and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to manganese.

Manganese and its compounds have moderate acute toxicity to aquatic life. Manganese is considered essential for plant and animal life. However, insufficient data are available on the acute effects of excessive manganese contamination on the other ecosystems (plants, birds, or land animals).

🕒 *Chronic Ecological Effects*

Chronic (long-term) toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals.

Manganese and its compounds have moderate chronic toxicity to aquatic life. Manganese is considered essential for plant and animal life. However, insufficient data are available on the chronic effects of excessive manganese contamination on the other ecosystems (plants, birds, or land animals).

💧 *Water Solubility*

Manganese and its compounds vary in their solubility in water from very soluble to nearly insoluble. In water, it reacts and decomposes to form explosive hydrogen gas.

🕒 *Persistence in the Environment*

Manganese and its compounds are highly persistent in water, with a half-life greater than 200 days. The half-life of a pollutant is the amount of time it takes for one half of the chemical to be degraded. Manganese is also naturally present in terrestrial soils and aquatic sediments.

🐟 *Bioaccumulation in Aquatic Organisms*

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans.

The concentration of manganese found in fish tissues is expected to be about the same as the average concentration of manganese in the water from which the fish was taken.

🛡️ *Recommended Risk-Reduction Measures*

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in a leak or spill of manganese dusts or powders into the environment. The correct use of labeling on all containers, trucks, and rail cars will enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of manganese should be segregated from incompatible chemicals to minimize the risk of cross-contamination or contact. Care should be taken to prevent physical damage to storage containers. Also, dusty conditions must be avoided in storage and use areas. When manganese comes into contact with water, it will readily liberate excessive amounts of highly flammable and explosive hydrogen gas.

If a spill or leak to the environment has occurred, fire department, emergency response and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those trained in proper spill containment procedures using non-sparking tools. Contaminated soils should be re-

moved for decontamination and replaced with clean soil. If manganese should contact the water table, aquifer, or navigable waterway, time is of the essence. It will slowly decompose in water and total remediation may not be possible. The local and/or state emergency response authorities may require notification. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of manganese.

If manganese is spilled or leaked, the following specific steps are recommended:

- ☑ Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened for normal work.
- ☑ Remove all ignition sources from area.
- ☑ Ventilate area of spill or leak.
- ☑ Collect powdered materials in the safest manner possible and deposit in sealed containers. Recommend using a vacuum equipped with a high-efficiency particulate air (HEPA) filter. Do not dry sweep (generates airborne dusts). Keep water away (do NOT damp mop residues).
- ☑ It may be necessary to dispose of manganese as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving manganese can present a significant threat to business operations. The loss or damage of equipment or facilities can significantly affect fiscal viability. Lawsuits that may result from personnel injury/death, public exposures, and/or environmental contamination will also require a serious expenditure of resources. Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business. Always remember that anytime the terms "cancer," "carcinogen," or "reproductive hazard" are used, public hysteria, emotion, and ignorance can run equally high. This should be carefully considered during the development of public relations policies.

🕒 Recommended Risk-Reduction Measures

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures for responding to chemical incidents. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

MANGANESE CARBONATEMnCO₃

CAS: 598-62-9

**IDENTIFICATION AND TYPICAL USES**

Manganese carbonate appears as rose-colored, rhombohedral crystals. The precipitated form is a white crystalline solid. Manganese carbonate gradually turns light brown on exposure to air as it decomposes to form manganese oxide and carbon dioxide. It is used as a pigment in paints, as a drier for varnishes, as a source of acid-soluble manganese, as a nutrient for plants and crops, in feeds, in the making of ceramics, in the production of ferrite, in the production of manganese salts and pharmaceuticals (medicines to stimulate blood formation).

RISK ASSESSMENT: HEALTH***General Assessment***

Manganese carbonate does not absorb well through the digestive or respiratory processes. It therefore presents very low acute toxicity. However, in large or chronic doses (1 to 2 years of exposure) by *inhalation* or *ingestion*, manganese poisoning can be quite severe. There is little information in the references regarding its carcinogenic, mutagenic, or teratogenic capabilities in animals or humans.

Inhalation of manganese carbonate over prolonged periods of time can lead to the development of manism. The early symptoms are difficult to recognize because they are generally nonspecific in nature and may occur gradually over a long period of time. It usually begins with the nonspecific neurologic symptoms such as headache, general apathy, weakness of the legs, progressing to psychosis, with final symptoms similar to that of Parkinson's disease. There can be pain and stiffness in the back and joints, anorexia, weakness, sleepiness, muscle spasms, psychosis, emotional swings (laughter or crying for no apparent reason), euphoria, mental confusion, hallucinations, speech disturbances, muscle rigidity, salivation, trembling, staggering gait, and profuse sweating.

☠ *Acute Health Effects*

Acute poisoning with manganese carbonate are rare. The following acute (short-term) health effects may occur immediately or shortly after human exposure to manganese carbonate:

- Skin:** Possible irritation and dermatitis (in some individuals).
- Eye:** Irritation to the eye and associated tissues. It can cause conjunctivitis and corneal damage.
- Lung:** Irritation of the mucosa of the eyes, nose, throat, and respiratory tract.
- CNS:** There may be no noticeable acute effects. However, large doses may result in generally adverse nervous system effects.

☠* *Chronic Health Effects*

The following chronic (long-term) health effects may occur at some time after exposure to manganese carbonate and can last for months or even years:

Cancer Hazards: According to the references, manganese carbonate has not been shown to cause cancer in test animals. Its human carcinogenic potential is unknown.

Reproductive Hazard: According to the references, manganese carbonate has not been adequately tested for its ability to cause adverse reproductive effects in test animals.

Other Chronic Effects: Prolonged or repeated exposure can damage the central nervous system and cause impaired mental function and degenerative brain changes with personality disorders and physical changes in motor control, vision, and other body functions.

🚫 *Recommended Risk-Reduction Measures*

While manganese is an essential mineral in human nutrition, the base element and the carbonate as well can be extremely toxic under certain exposure conditions and personnel should, therefore, avoid direct occupational contact with manganese carbonate. If a less toxic material or compound cannot be substituted for manganese carbonate, then *engineering controls* are the most effective method of reducing exposures. The best protection is to enclose operations and/or provide local exhaust ventilation at the site of manganese carbonate dust release. While not always operationally feasible, isolating operations can also reduce exposure. Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around manganese carbonate. The exposure ceiling for manganese is relatively low ($5\text{mg}/\text{m}^3$) and difficult to accurately monitor. For low or transient exposures, a chemical cartridge respirator equipped with a high-efficiency particulate air (HEPA) filter and a dust/mist pre-filter may provide adequate respiratory protection. Better protection is obtained using a supplied-air respirator operated in continuous flow mode or a self-contained breathing apparatus (SCBA) with full facepiece operated in pressure demand. If a full facepiece is not available, then chemical/dust goggles should be worn to protect the eyes. A face shield and protective apron should also be worn. To prevent hand and skin exposures, gloves should be used. Glove manufacturers should be contacted *before* selections are made.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with manganese carbonate.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where manganese carbonate is used or stored.

Before beginning employment working with manganese carbonate, and at regular intervals thereafter (e.g., annually), those personnel with frequent or potentially high exposures should be provided the following recommended medical tests:

- Complete blood count (establish baseline).

If symptoms develop or overexposure is suspected, consider the following additional tests:

- Complete blood count (compare to baseline).

- Neurological examination.
- Lung function tests.

Any evaluation should include a careful history of past and present symptoms with an examination. Medical tests that simply look for existing damage are not a substitute for controlling exposures.

Other methods to reduce exposure include:

- Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not used, respiratory protection should be mandatory.
- Always ensure that proper protective clothing is worn when using chemical substances. Proper maintenance and care of protective equipment is essential to its proper function.
- Wash thoroughly immediately after exposure to manganese carbonate and at the end of the work shift or before eating, drinking, or smoking.
- Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of manganese carbonate should be communicated to all exposed and potentially exposed workers.
- Eye wash stations should be provided in the immediate work area for emergency use. If there is a possibility of skin exposure to manganese carbonate, emergency shower facilities should be provided in the immediate area.
- Workers whose clothing has been contaminated by manganese carbonate should change into clean clothes before leaving work. Never wear contaminated clothing home where family members can be exposed. Contaminated work clothing should be laundered only by individuals who have been informed of the hazards of exposure to manganese carbonate.

RISK ASSESSMENT: ENVIRONMENT

General Assessment

As a naturally occurring mineral, manganese itself poses very little threat to the environment. However, accidental spills or releases to the environment can occur during transportation, storage, disposal, or destruction of manganese carbonate. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical sub-

stance. Accidental spills, large or small, where manganese carbonate contacts incompatible commodities can result in release of toxic products (depending upon conditions of spill), and possible contamination of the surrounding environmental mediums (water, soil, and air).

Manganese carbonate is considered a noncombustible solid. It reacts with acid to generate toxic carbon dioxide. It is also incompatible with many other materials, including sulfur dioxide which oxidizes to the even more toxic sulfur trioxide. It will cause the violent decomposition of hydrogen peroxide (>52% solutions). Extreme caution is always required in handling, storage, transportation, and disposal of manganese carbonate. These characteristics also require special consideration during any emergency situation involving a leak or spill of manganese carbonate powder or dust. Should manganese carbonate ever come into contact with these various incompatible substances either during use, transportation, storage, or disposal, violent and even explosive reactions are possible.

Manganese occurs naturally in the environment (terrestrial soils and aquatic sediments) and may enter the environment as a result of industrial and municipal waste treatment plant discharges and from accidental spills.

☠ *Acute Ecological Effects*

Acute (short-term) toxic effects may include the death of animals, birds, or fish and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to manganese.

Manganese and its compounds have moderate acute toxicity to aquatic life. Manganese is considered essential for plant and animal life. However, insufficient data are available on the acute effects of excessive manganese carbonate contamination on plants, birds, or land animals.

🕒 *Chronic Ecological Effects*

Chronic (long-term) toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals.

Manganese and its compounds have moderate chronic toxicity to aquatic life. Manganese is considered essential for plant and animal life. However, insufficient data are available on the chronic effects of

excessive manganese contamination on plants, birds, or land animals.

💧 *Water Solubility*

Manganese and its compounds vary in their solubility in water from very soluble to nearly insoluble. In water, manganese reacts and decomposes to form explosive hydrogen gas. Manganese carbonate easily dissolves in acidic water and becomes highly mobile.

🕒 *Persistence in the Environment*

Manganese and its compounds are highly persistent in water, with a half-life greater than 200 days. The half-life of a pollutant is the amount of time it takes for one half of the chemical to be degraded. Manganese is also naturally present in terrestrial soils and aquatic sediments.

🐟 *Bioaccumulation in Aquatic Organisms*

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans.

The concentration of manganese found in fish tissues is expected to be about the same as the average concentration of manganese found in the water from which the fish was taken.

🛑 *Recommended Risk-Reduction Measures*

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in a leak or spill of manganese carbonate dusts or powders into the environment. The correct use of labeling on all containers, trucks, and rail cars will enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of manganese carbonate should be segregated from incompatible chemicals to minimize the risk of cross-contamination or contact. Care should be taken to prevent physical damage to storage containers. Also, dusty conditions must be avoided in storage and use areas.

If a spill or leak to the environment has occurred, fire department, emergency response and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those trained in proper spill containment procedures using non-sparking tools. Contaminated soils should be re-

moved for decontamination and replaced with clean soil. If manganese carbonate should contact the water table, aquifer, or navigable waterway, time is of the essence. It will slowly dissolve in water and total remediation may not be possible. The local and/or state emergency response authorities may require notification. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of manganese carbonate.

If manganese carbonate is spilled or leaked, the following specific steps are recommended:

- ☑ Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened for normal work.
- ☑ Ventilate area of spill or leak.
- ☑ Collect powdered materials in the safest manner possible and deposit in sealed containers. Recommend using a vacuum equipped with a high-efficiency particulate air (HEPA) filter. Do not dry sweep (generates airborne dusts).
- ☑ It may be necessary to dispose of manganese carbonate as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving manganese carbonate can present a significant threat to business operations. The loss or damage of equipment or facilities can significantly affect fiscal viability. Lawsuits that may result from personnel injury/death, public exposures, and/or environmental contamination will also require a serious expenditure of resources. Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business.

🔹 *Recommended Risk-Reduction Measures*

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures for responding to chemical incidents. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and

policies should be developed, approved, and implemented long before any need for such arises.

MANGANESE DIOXIDEMnO₃

CAS: 1313-13-9

**IDENTIFICATION AND TYPICAL USES**

Manganese dioxide appears as a black or brownish-black fine powder or crystals, or, it can appear as steel-gray lumps. There is no odor. It is used as an oxidizing agent, in some dry cell batteries (African and synthetic types), in the manufacture of pyrotechnics, in matches, as a catalysts, a laboratory reagent, in textile dyeing, and as a source of metallic manganese.

RISK ASSESSMENT: HEALTH**General Assessment**

Even though manganese is an essential mineral in human nutrition, it can also be toxic by *inhalation* of its fumes and/or by *ingestion* of the powders and dusts. While manganese has been shown to cause tumors in experimental test animals with mutation data also reported, the exact nature of manganese dioxide's human carcinogenic properties is unknown.

Inhalation of manganese dioxide dusts can irritate the respiratory tract with progression to lung damage, pleuritis, bronchitis, and possible respiratory infections. The fumes can cause acute or chronic poisoning with primary effects on the immune system characterized by symptoms of metal fume fever. These can include fever, chills, general weakness, body aches, frontal headache, blurred vision, back pain and stiffness, muscular cramps, shallow and labored respiration, dryness in the mouth and throat with intense thirst, dry cough, metallic taste, and tightness in the chest occurring several hours after exposure. Lung irritation can become severe with inflammation causing manganese dioxide pneumonitis. Other effects of central nervous system depression include headache, insomnia, changes in personality, emotions, and attitude, irritability, inappropriate laughter or crying, hallucinations, effects on vision (double vision, blurred vision), uncontrolled impulse behavior, euphoria, excessive salivation, trembling, staggering gait,

clumsiness, and signs and symptoms normally associated with Parkinson's disease.

☠ Acute Health Effects

The following acute (short-term) health effects may occur immediately or shortly after human exposure to manganese dioxide:

Skin: Manganese dioxide appears to be completely innocuous to intact (unbroken) skin.

Eye: Irritation to the eye and associated tissues. Effects appear to be minor and temporary.

Lung: Irritation of the mucosa of the eyes, nose, throat, and respiratory tract.

CNS: Breathing heated fumes can cause metal fume fever with specific action on the central nervous system.

☘ Chronic Health Effects

The following chronic (long-term) health effects may occur at some time after exposure to manganese dioxide and can last for months or even years:

Cancer Hazards: According to the references, manganese has been shown to cause tumors in test animals. There are no reports of the specific carcinogenic properties of manganese dioxide.

Reproductive Hazard: According to the references, there is some limited evidence that chronic overexposure to manganese dioxide may cause adverse reproductive effects in test animals.

Other Chronic Effects: Prolonged or repeated exposure can damage the central nervous system and cause impaired mental function and degenerative brain changes with personality disorders, emotional instability, awkward gestures, and physical changes in motor control, vision, and other body functions.

🛡 Recommended Risk-Reduction Measures

While manganese is an essential mineral in human nutrition, the base mineral as well as many of its compounds (including in the dioxide) can be extremely toxic under certain exposure conditions. Personnel should, therefore, avoid direct occupational contact with manganese dioxide. If a less toxic material or compound cannot be substituted for manganese dioxide, then *engineering controls* are the most effective method of reducing exposures. The best protection is to enclose operations and/or provide local exhaust ventilation at the site of manganese dioxide dust release. While not always operationally feasible, isolating operations can also reduce exposure. Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around manganese dioxide. The exposure ceiling for manganese is relatively low ($5\text{mg}/\text{m}^3$) and difficult to accurately monitor. For low or transient exposures, a chemical cartridge respirator equipped with a high-efficiency particulate air (HEPA) filter and a dust/mist pre-filter may provide adequate respiratory protection. Better protection is obtained using a supplied-air respirator operated in continuous flow mode or a self-contained breathing apparatus (SCBA) with full facepiece operated in pressure demand. If a full facepiece is not available, then chemical/dust goggles should be worn to protect the eyes. A face shield and protective apron should also be worn. To prevent hand and skin exposures, gloves should be used. Glove manufacturers should be contacted *before* selections are made.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with manganese dioxide.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where manganese dioxide is used or stored.

Before beginning employment working with manganese dioxide, and at regular intervals thereafter (e.g., annually), those personnel with frequent or potentially high exposures should be provided the following recommended medical tests:

- Complete blood count (establish baseline).
 - Complete examination of the nervous system.
 - Lung function tests (may be normal if the person is not having an attack at the time of the test)
 - Kidney function tests.
- If symptoms develop or overexposure is suspected, consider the following additional tests:
- Complete blood count (compare to baseline).
 - Consider chest X-ray after acute overexposure.
 - Lung function tests.
- Any evaluation should include a careful history of past and present symptoms with an examination. Medical tests that simply look for existing damage are not a substitute for controlling exposures. Also, since smoking causes heart disease, lung cancer, emphysema, and other respiratory diseases, smokers exposed to manganese dioxide may experience symptoms more rapidly than non-smokers under the same conditions of exposure. Prudent risk management requires careful consideration of *all* factors which may be causing exposure symptoms in the workplace.
- Other methods to reduce exposure include:
- Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not used, respiratory protection should be mandatory.
 - Always ensure that proper protective clothing is worn when using chemical substances. Proper maintenance and care of protective equipment is essential to its proper function.
 - Wash thoroughly immediately after exposure to manganese dioxide and at the end of the work shift or before eating, drinking, or smoking.
 - Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of manganese dioxide should be communicated to all exposed and potentially exposed workers.
 - Eye wash stations should be provided in the immediate work area for emergency use. If there is a possibility of skin exposure to manganese dioxide, emergency shower facilities should be provided.
 - Workers whose clothing has been contaminated by manganese dioxide should change into clean clothes before leaving work. Never wear contaminated clothing home where family members can be exposed. Contaminated work clothing

should be laundered only by individuals who have been informed of the hazards of exposure to manganese dioxide.

RISK ASSESSMENT: ENVIRONMENT

General Assessment

As a naturally occurring mineral, manganese poses very little threat to the environment. However, accidental spills or releases to the environment can occur during transportation, storage, disposal, or destruction of manganese dioxide. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance. Accidental spills, large or small, where manganese dioxide contacts incompatible commodities can result in release of toxic products (depending upon conditions of spill), and possible contamination of the surrounding environmental mediums (water, soil, and air).

Manganese dioxide is considered a noncombustible solid. However, it is a powerful oxidizer and it can greatly accelerate the burning of ordinary combustible materials. It is incompatible with sulfur, sulfides, phosphides, hypophosphites, chlorates, and peroxides. It can also react violently in contact with other oxidizers. Extreme caution is always required in handling, storage, transportation, and disposal of manganese dioxide. These characteristics also require special consideration during any emergency situation involving a leak or spill of manganese dioxide powder or dust. Should manganese dioxide ever come into contact with these various incompatible substances either during use, transportation, storage, or disposal, violent and even explosive reactions are possible.

Manganese occurs naturally in many minerals that are widely distributed in the earth's crust and, in trace amounts, is an essential element for both plants and animals. The wide variety of possible manganese compounds may enter the environment from natural and industrial sources.

☠ Acute Ecological Effects

Acute (short-term) toxic effects may include the death of animals, birds, or fish and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to manganese dioxide.

Manganese and its compounds have moderate acute toxicity to aquatic life. While manganese dioxide is considered essential for plant and animal life, insufficient data are available on the acute effects of

excessive manganese dioxide contamination on the other ecosystems (plants, birds, or land animals).

☠ Chronic Ecological Effects

Chronic (long-term) toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals.

Manganese and its compounds have moderate chronic toxicity to aquatic life. Manganese dioxide is considered essential for plant and animal life. However, insufficient data are available on the chronic effects of excessive manganese dioxide contamination on the other ecosystems (plants, birds, or land animals).

💧 Water Solubility

Manganese and its compounds vary in their solubility in water from very soluble to nearly insoluble. In water, it reacts and decomposes to form explosive hydrogen gas.

⌚ Persistence in the Environment

Manganese and its compounds are highly persistent in water, with a half-life greater than 200 days. The half-life of a pollutant is the amount of time it takes for one half of the chemical to be degraded. Manganese is also naturally present in terrestrial soils and aquatic sediments.

🌊 Bioaccumulation in Aquatic Organisms

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans.

The concentration of manganese dioxide found in fish tissues is expected to be about the same as the average concentration of manganese dioxide in the water from which the fish was taken.

🛑 Recommended Risk-Reduction Measures

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in a leak or spill of manganese dioxide dusts or powders into the environment. The correct use of labeling on all containers, trucks, and rail cars will enable emergency

responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of manganese dioxide should be segregated from incompatible chemicals to minimize the risk of cross-contamination or contact. Care should be taken to prevent physical damage to storage containers. Also, dusty conditions must be avoided in storage and use areas.

If a spill or leak to the environment has occurred, fire department, emergency response and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those trained in proper spill containment procedures. Contaminated soils should be removed for decontamination and replaced with clean soil. If manganese dioxide should contact the water table, aquifer, or navigable waterway, response actions should be prompt. The local and/or state emergency response authorities may require notification. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of manganese dioxide.

If manganese dioxide is spilled or leaked, the following specific steps are recommended:

- ☑ Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened for normal work.
- ☑ Remove ignition sources and ventilate area.
- ☑ Cover spilled materials with clean, moist sand. Mix and collect powdered materials in the safest manner possible and deposit in sealed containers. Recommend using a vacuum equipped with a high-efficiency particulate air (HEPA) filter on residues. Do NOT dry sweep (generates airborne dusts).
- ☑ It may be necessary to dispose of manganese dioxide as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving manganese dioxide can present a significant threat to business operations. The loss or damage of equipment or facilities can significantly affect fiscal viability. Lawsuits that may

result from personnel injury/death, public exposures, and/or environmental contamination will also require a serious expenditure of resources. Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business. Always remember that anytime the terms "cancer," "carcinogen," or "reproductive hazard" are used, public hysteria, emotion, and ignorance can run equally high. This should be carefully considered during the development of public relations policies.

Recommended Risk-Reduction Measures

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures for responding to chemical incidents. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

The fumes can cause metal fume fever with, chills, nausea, weakness, headache, fever, blurred vision, back stiffness and pain, muscle pain, shallow respiration, dryness in mouth and throat, intense thirst, metallic taste, chest tightness, and Mn pneumonitis. It can also lead to degenerative brain effects with symptoms similar to Parkinson's disease. It may also cause methemoglobinemia and subsequent cyanosis. EYES & SKIN: Causes skin and eye irritation and burns. There can be conjunctivitis, corneal damage. INGESTION: Large doses can cause gastrointestinal irritation and other effects similar to inhalation. | | | | |
| Carcinogenicity Unknown Human Questioned Animal | NTP Listed? No | IARC Cancer Review Group? No | OSHA Regulated? No | Target Organs? Respiratory system, eyes, skin, CNS, kidneys, blood. |
| Medical Conditions Generally Aggravated by Exposure Neurologic, psychological, or pulmonary disorders, and anemia may be aggravated by exposure. | | | | |
| Emergency and First-aid Procedures Eye contact: Do not allow victim to keep eyes tightly shut. Flush immediately with water for 15 minutes (minimum); seek medical attention. Skin contact: Remove all contaminated clothing. Immediately wash area with flooding amounts of water. For reddened or blistered skin, seek medical assistance. For inhalation: Remove the person from exposure. Provide respiratory assistance and CPR. Transfer to medical facility. Observe for 48 hours for lung effects. If swallowed: Seek medical attention. | | | | |
| SECTION VII - PRECAUTIONS FOR SAFE HANDLING AND USE | | | | |
| Steps to be Taken in Case Material is Released or Spilled Collect powdered materials in most convenient and safe manner and deposit in clean, dry, sealed, metal containers. Dry sweep not recommended. Use HEPA vacuum. For solutions, absorb in vermiculite and place in sealed drum. Ventilate area of spill. Restrict those not involved in cleanup from entering area. | | | | |
| Preferred Waste Disposal Method No Citation. | | | | |
| Precautions to be Taken in Handling and Storage Store to avoid contact with incompatible materials. Prevent physical damage to containers. Keep containers tightly closed. Keep sources of heat away. | | | | |
| Other Precautions and Warnings Avoid excessive dust generation in storage and handling areas. | | | | |
| SECTION VIII - CONTROL MEASURES AND PERSONAL PROTECTIVE EQUIPMENT | | | | |
| Respiratory Protection (<i>specify type</i>) For dust exposures, use a respirator with a HEPA filter; otherwise, use a supplied-air respirator or a self-contained breathing apparatus with full facepiece operated in positive pressure mode. | | | | |
| Ventilation Local exhaust (preferred) at site of chemical work or general ventilation. | | | | |
| Protective Gloves Impervious Material | | Eye Protection Chemical/Dust Goggles or Face Mask | | Other Protective Clothing Protective Apron, Boots |
| Work/Hygiene Practices Always wash hands thoroughly after using chemical; never bring food, drink, or smoking materials into vicinity of chemicals. | | | | |

MANGANESE NITRATEMn(NO₃)₂•6H₂O

CAS: 10377-66-9

**IDENTIFICATION AND TYPICAL USES**

Manganese nitrate appears as colorless, pink, or rose-colored deliquescent crystalline solid with no detectable odor. It is used in ceramics, as an intermediate, as a catalyst, and as a source of magnesium dioxide.

RISK ASSESSMENT: HEALTH**General Assessment**

Manganese is highly toxic to humans by *inhalation* or *ingestion*. High exposures can produce quite severe poisoning with action on the respiratory and central nervous system, depending upon the conditions of exposure. There are no reports of any carcinogenic, mutagenic, or teratogenic effects in humans or animals.

Inhalation of manganese nitrate dusts can cause irritation to the eyes, nose, throat, and mucosa of the respiratory tract. There can be dryness of the nose (with nosebleeds), throat, and bronchial passages producing cough and phlegm. High exposures can lead to a dangerous buildup of fluid in the lungs (pulmonary edema) which can be fatal. Symptoms may not develop for up to 48 hours or more, thereby creating a false sense of security with regard to health exposure risk. Exposure over prolonged periods of time can lead to the development of manganism. The early symptoms are difficult to recognize because they are generally nonspecific in nature and may occur gradually over a long period of time. It often begins with nonspecific neurologic symptoms such as headache, general apathy, weakness of the legs, progressing to psychosis, with final symptoms similar to that of Parkinson's disease. There can be pain and stiffness in the back and joints, anorexia, weakness, sleepiness, muscle spasms, psychosis, anorexia, emotional swings (laughter or crying for no apparent reason), euphoria, mental confusion, hallucinations, speech disturbances, muscle rigidity, excessive salivation, trembling and

tremors, staggering gait and balance disturbances, and profuse sweating.

☠ Acute Health Effects

Acute poisoning with manganese nitrate is rare. The following acute (short-term) health effects may occur immediately or shortly after human exposure to manganese nitrate:

Skin: Irritation, burns, and blisters.

Eye: Irritation to the eye and associated tissues. It can cause burns (especially the concentrated solutions), conjunctivitis, and corneal damage.

Lung: Irritation of the mucosa of the eyes, nose, throat, and respiratory tract. Can cause dryness, nosebleeds, cough with phlegm, and potentially fatal pulmonary edema.

CNS: There may be no noticeable acute effects. However, large doses may result in generally adverse nervous system effects.

☘ Chronic Health Effects

The following chronic (long-term) health effects may occur at some time after exposure to manganese nitrate and can last for months or even years:

Cancer Hazards: According to the references, manganese nitrate has not been adequately tested for its ability to cause cancer in test animals.

Reproductive Hazard: According to the references, manganese nitrate has not been adequately tested for its ability to cause adverse reproductive effects in test animals.

Other Chronic Effects: Prolonged or repeated exposure can damage the central nervous system and cause impaired mental function and degenerative brain changes with personality disorders and physical changes in motor control, vision, and other body functions. High or repeated exposures may damage the lungs, cause changes in the blood

(methemoglobinemia), and damage the kidneys or liver.

🔊 **Recommended Risk-Reduction Measures**

While manganese is an essential mineral in human nutrition, the base element and the nitrate can be extremely toxic under certain exposure conditions and personnel should, therefore, avoid direct occupational contact with manganese nitrate. If a less toxic material or compound cannot be substituted for manganese nitrate, then *engineering controls* are the most effective method of reducing exposures. The best protection is to enclose operations and/or provide local exhaust ventilation at the site of manganese nitrate dust release. While not always operationally feasible, isolating operations can also reduce exposure. Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around manganese nitrate. The exposure ceiling for manganese compounds is relatively low ($5\text{mg}/\text{m}^3$) and difficult to accurately monitor. For low or transient exposures, a chemical cartridge respirator equipped with a high-efficiency particulate air (HEPA) filter and a dust/mist pre-filter may provide adequate respiratory protection. Better protection is obtained using a supplied-air respirator operated in continuous flow mode or a self-contained breathing apparatus (SCBA) with full facepiece operated in pressure demand. If a full facepiece is not available, then chemical/dust goggles should be worn to protect the eyes. A face shield and protective apron should also be worn. To prevent hand and skin exposures, gloves should be used. Glove manufacturers should be contacted *before* selections are made.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with manganese nitrate.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where manganese nitrate is used or stored.

Before beginning employment working with manganese nitrate, and at regular intervals thereafter (e.g., annually), those personnel with frequent or potentially high exposures should be provided the following recommended medical tests:

- Complete blood count (establish baseline).
 - Complete examination of the nervous system.
 - Lung function tests (may be normal if the person is not having an attack at the time of the test).
 - Kidney function tests.
- If symptoms develop or overexposure is suspected, consider the following additional tests:
- Complete blood count (compare to baseline).
 - Consider chest X-ray after acute overexposure (may be negative if taken immediately after exposure due to delayed onset of pulmonary edema).
 - Lung function tests.
- Any evaluation should include a careful history of past and present symptoms with an examination. Medical tests that simply look for existing damage are not a substitute for controlling exposures. Also, since smoking causes heart disease, lung cancer, emphysema, and other respiratory diseases, smokers exposed to manganese nitrate may experience symptoms more rapidly than non-smokers under the same conditions of exposure. Prudent risk management requires careful consideration of *all* factors which may be causing exposure symptoms in the workplace.
- Other methods to reduce exposure include:
- Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not used, respiratory protection should be mandatory.
 - Always ensure that proper protective clothing is worn when using chemical substances. Proper maintenance and care of protective equipment is essential to its function. Therefore, ensure that personnel have received the necessary training on personal protective equipment use and care.
 - Wash thoroughly immediately after exposure to manganese nitrate and at the end of the work shift or before eating, drinking, or smoking.
 - Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of manganese nitrate should be communicated to all exposed and potentially exposed workers.
 - Eye wash stations should be provided in the immediate work area for emergency use. If there is a possibility of skin exposure to manganese nitrate, emergency shower facilities should be provided in the immediate area.

- ☑ Workers whose clothing has been contaminated by manganese nitrate should change into clean clothes before leaving work. Never wear contaminated clothing home where family members can be exposed. Contaminated work clothing should be laundered only by individuals who have been informed of the hazards of exposure to manganese nitrate.

RISK ASSESSMENT: ENVIRONMENT

General Assessment

As a naturally occurring mineral, manganese itself poses very little threat to the environment. However, accidental spills or releases to the environment can occur during transportation, storage, disposal, or destruction of manganese nitrate. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance. Accidental spills, large or small, where manganese nitrate contacts incompatible commodities can result in release of toxic products (depending upon conditions of spill), and possible contamination of the surrounding environmental mediums (water, soil, and air).

Manganese nitrate is considered a noncombustible solid. But it will react violently in contact with ordinary combustible materials. Extreme caution is always required in handling, storage, transportation, and disposal of manganese nitrate. These characteristics also require special consideration during any emergency situation involving a leak or spill of manganese nitrate powder or dust. Should manganese nitrate ever come into contact with organic materials either during use, transportation, storage, or disposal, violent and even explosive reactions are possible.

Manganese occurs naturally in many minerals that are widely distributed in the earth's crust and, in trace amounts, is an essential element for both plants and animals. The wide variety of possible manganese compounds may enter the environment from natural and industrial sources.

☠ *Acute Ecological Effects*

Acute (short-term) toxic effects may include the death of animals, birds, or fish and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to manganese.

Manganese and its compounds have moderate acute toxicity to aquatic life. While manganese is considered essential for plant and animal life, insuffi-

cient data are available on the acute effects of excessive manganese nitrate contamination on plants, birds, or land animals.

☼ *Chronic Ecological Effects*

Chronic (long-term) toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals.

Manganese and its compounds have moderate chronic toxicity to aquatic life. Manganese is considered essential for plant and animal life. However, insufficient data are available on the chronic effects of excessive manganese contamination on plants, birds, or land animals.

💧 *Water Solubility*

Manganese and its compounds vary in their solubility in water from very soluble to nearly insoluble. In water, manganese reacts and decomposes to form explosive hydrogen gas. Manganese nitrate easily dissolves in water and becomes highly mobile.

⌚ *Persistence in the Environment*

Manganese and its compounds are highly persistent in water, with a half-life greater than 200 days. The half-life of a pollutant is the amount of time it takes for one half of the chemical to be degraded. Manganese is also naturally present in terrestrial soils and aquatic sediments.

🌊 *Bioaccumulation in Aquatic Organisms*

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans.

The concentration of manganese found in fish tissues is expected to be about the same as the average concentration of manganese found in the water from which the fish was taken.

🛡️ *Recommended Risk-Reduction Measures*

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in a leak or spill of manganese nitrate dusts or powders into the environment. The correct use of labeling on all con-

tainers, trucks, and rail cars will enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of manganese nitrate should be segregated from incompatible chemicals to minimize the risk of cross-contamination or contact. Care should be taken to prevent physical damage to storage containers. Also, dusty conditions must be avoided in storage and use areas.

If a spill or leak to the environment has occurred, fire department, emergency response and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those trained in proper spill containment procedures. Contaminated soils should be removed for decontamination and replaced with clean soil. If manganese nitrate should contact the water table, aquifer, or navigable waterway, response activities should be prompt. The local and/or state emergency response authorities may require notification. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of manganese nitrate.

If manganese nitrate is spilled or leaked, the following specific steps are recommended:

- Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened for normal work.
- Ventilate area of spill or leak.
- Collect powdered materials in the safest manner possible and deposit in sealed containers. Recommend using a vacuum equipped with a high-efficiency particulate air (HEPA) filter. Do not dry sweep (generates airborne dusts). Absorb solution spills with vermiculite or other material, collect, and place in sealed drum for disposal.
- It may be necessary to dispose of manganese nitrate as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving manganese nitrate can present a significant threat to business operations. The loss or damage of equipment or facilities can sig-

nificantly affect fiscal viability. Lawsuits that may result from personnel injury/death, public exposures, and/or environmental contamination will also require a serious expenditure of resources. Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business.

Recommended Risk-Reduction Measures

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures for responding to chemical incidents. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

| Medical Conditions Generally Aggravated by Exposure Neurologic, psychological, or pulmonary disorders, and anemia may be aggravated by exposure. | | | | |
| Emergency and First-aid Procedures Eye contact: Do not allow victim to keep eyes tightly shut. Flush immediately with water for 15 minutes (minimum); seek medical attention. Skin contact: Remove all contaminated clothing. Immediately wash area with flooding amounts of water. For reddened or blistered skin, seek medical assistance. For inhalation: Remove the person from exposure. Provide respiratory assistance and CPR. Transfer to medical facility. If swallowed: Seek medical attention. Rinse mouth with water. Give 1 to 2 glasses of water and induce vomiting until vomit is clear. Never give anything by mouth to a convulsing person. | | | | |
| SECTION VII - PRECAUTIONS FOR SAFE HANDLING AND USE | | | | |
| Steps to be Taken in Case Material is Released or Spilled Collect powdered materials in most convenient and safe manner and deposit in clean, dry, sealed, metal containers. Dry sweep not recommended. Use HEPA vacuum. For solutions, absorb in vermiculite and place in sealed drum. Ventilate area of spill. Restrict those not involved in cleanup from entering area. | | | | |
| Preferred Waste Disposal Method No citation. | | | | |
| Precautions to be Taken in Handling and Storage Store to avoid contact with incompatible materials. Prevent physical damage to containers. Keep containers tightly closed. Keep sources of heat away. | | | | |
| Other Precautions and Warnings Avoid excessive dust generation in storage and handling areas. Personnel should be trained on the proper precautions for working with manganese sulfate compounds <i>before</i> initial assignment. | | | | |
| SECTION VIII - CONTROL MEASURES AND PERSONAL PROTECTIVE EQUIPMENT | | | | |
| Respiratory Protection (<i>specify type</i>) For dust exposures, use a respirator with a HEPA filter; otherwise, use a supplied-air respirator or a self-contained breathing apparatus with full facepiece operated in positive pressure mode. | | | | |
| Ventilation Local exhaust (preferred) at site of chemical work or general ventilation. | | | | |
| Protective Gloves Impervious Material | Eye Protection Chemical/Dust Goggles or Face Mask | Other Protective Clothing Protective Apron, Boots | | |
| Work/Hygiene Practices Always wash hands thoroughly after using chemical; never bring food, drink, or smoking materials into vicinity of chemicals. | | | | |

MANGANESE SULFATEMnSO₄

CAS: 7785-87-7

**IDENTIFICATION AND TYPICAL USES**

Manganese sulfate appears as pink, red, or rose-colored, translucent efflorescent prisms or crystals with no detectable odor. It is used in fertilizers and fungicides, as a feed additive, in paints and varnishes, in ceramics, in textile dyes, medicines, for ore flotation, as a catalyst in viscose process, and in the manufacture of synthetic manganese dioxide.

RISK ASSESSMENT: HEALTH***General Assessment***

Manganese sulfate does not absorb well through the digestive or respiratory processes. It therefore presents very low acute toxicity. However, in large or chronic doses (1 to 2 years of exposure) by *inhalation* or *ingestion*, manganese poisoning can be quite severe. It is considered a questionable carcinogen by at least one source (Lewis 1992) with experimental neoplastic and mutagenic data reported. It has also been shown to cause experimental teratogenic effects. The data are inconclusive and conflicting with regard to its human carcinogenic potential.

Inhalation of manganese sulfate over prolonged periods of time can lead to the development of mannanism. The early symptoms are difficult to recognize because they are generally nonspecific in nature and may occur gradually over a long period of time. It often begins with nonspecific neurologic symptoms such as headache, general apathy, weakness of the legs, progressing to psychosis, with final symptoms similar to that of Parkinson's disease. There can be pain and stiffness in the back and joints, anorexia, weakness, sleepiness, muscle spasms, psychosis, anorexia, emotional swings (laughter or crying for no apparent reason), euphoria, mental confusion, hallucinations, speech disturbances, muscle rigidity, excessive salivation, trembling and tremors, staggering gait and balance disturbances, and profuse sweating.

☠ *Acute Health Effects*

Acute poisoning with manganese sulfate is rare. The following acute (short-term) health effects may occur immediately or shortly after human exposure to manganese sulfate:

Skin: Possible irritation and dermatitis (in some individuals).

Eye: Irritation to the eye and associated tissues. It can cause conjunctivitis and corneal damage.

Lung: Irritation of the mucosa of the eyes, nose, throat, and respiratory tract.

CNS: There may be no noticeable acute effects. However, large doses may result in generally adverse nervous system effects.

☠* *Chronic Health Effects*

The following chronic (long-term) health effects may occur at some time after exposure to manganese sulfate and can last for months or even years:

Cancer Hazards: According to the references, manganese sulfate may cause cancer in test animals. Its human carcinogenic potential is unknown.

Reproductive Hazard: According to the references, manganese sulfate has been shown to cause adverse reproductive effects in test animals.

Other Chronic Effects: Prolonged or repeated exposure can damage the central nervous system and cause impaired mental function and degenerative brain changes with personality disorders and physical changes in motor control, vision, and other body functions.

🚫 *Recommended Risk-Reduction Measures*

While manganese is an essential mineral in human nutrition, the base element and the sulfate can be extremely toxic under certain exposure conditions and personnel should, therefore, avoid direct occupational contact with manganese sulfate. If a less toxic mate-

rial or compound cannot be substituted for manganese sulfate, then *engineering controls* are the most effective method of reducing exposures. The best protection is to enclose operations and/or provide local exhaust ventilation at the site of manganese sulfate dust release. While not always operationally feasible, isolating operations can also reduce exposure. Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around manganese sulfate. The exposure ceiling for manganese compounds is relatively low ($5\text{mg}/\text{m}^3$) and difficult to accurately monitor. For low or transient exposures, a chemical cartridge respirator equipped with a high-efficiency particulate air (HEPA) filter and a dust/mist pre-filter may provide adequate respiratory protection. Better protection is obtained using a supplied-air respirator operated in continuous flow mode or a self-contained breathing apparatus (SCBA) with full facepiece operated in pressure demand. If a full facepiece is not available, then chemical/dust goggles should be worn to protect the eyes. A face shield and protective apron should also be worn. To prevent hand and skin exposures, gloves should be used. Glove manufacturers should be contacted *before* selections are made.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with manganese sulfate.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where manganese sulfate is used or stored.

Before beginning employment working with manganese sulfate, and at regular intervals thereafter (e.g., annually), those personnel with frequent or potentially high exposures should be provided the following recommended medical tests:

- Complete blood count (establish baseline).
- Complete examination of the nervous system.
- Lung function tests (may be normal if the person is not having an attack at the time of the test)
- Kidney function tests.

If symptoms develop or overexposure is suspected, consider the following additional tests:

- Complete blood count (compare to baseline).

- Consider chest X-ray after acute overexposure.
- Lung function tests.

Any evaluation should include a careful history of past and present symptoms with an examination. Medical tests that simply look for existing damage are not a substitute for controlling exposures. Also, since smoking causes heart disease, lung cancer, emphysema, and other respiratory diseases, smokers exposed to manganese sulfate may experience symptoms more rapidly than non-smokers under the same conditions of exposure. Prudent risk management requires careful consideration of *all* factors which may be causing exposure symptoms in the workplace.

Other methods to reduce exposure include:

- Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not used, respiratory protection should be mandatory.
- Always ensure that proper protective clothing is worn when using chemical substances. Proper maintenance and care of protective equipment is essential to its function. Therefore, ensure that personnel have received the necessary training on personal protective equipment use and care.
- Wash thoroughly immediately after exposure to manganese sulfate and at the end of the work shift or before eating, drinking, or smoking.
- Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of manganese sulfate should be communicated to all exposed and potentially exposed workers.
- Eye wash stations should be provided in the immediate work area for emergency use. If there is a possibility of skin exposure to manganese sulfate, emergency shower facilities should be provided in the immediate area.
- Workers whose clothing has been contaminated by manganese sulfate should change into clean clothes before leaving work. Never wear contaminated clothing home where family members can be exposed. Contaminated work clothing should be laundered only by individuals who have been informed of the hazards of exposure to manganese sulfate.

RISK ASSESSMENT: ENVIRONMENT

General Assessment

As a naturally occurring mineral, manganese itself poses very little threat to the environment. However, accidental spills or releases to the environment can occur during transportation, storage, disposal, or destruction of manganese sulfate. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance. Accidental spills, large or small, where manganese sulfate contacts incompatible commodities can result in release of toxic products (depending upon conditions of spill), and possible contamination of the surrounding environmental mediums (water, soil, and air).

Manganese sulfate is considered a noncombustible solid. It will react and violently and cause the violent decomposition of hydrogen peroxide (>52% solutions). Contact with vibrations, X-rays, carbon monoxide, silicon dioxide, fluorine, copper, and lead, will greatly increase the toxicity of manganese sulfate. Extreme caution is always required in handling, storage, transportation, and disposal of manganese sulfate. These characteristics also require special consideration during any emergency situation involving a leak or spill of manganese sulfate powder or dust. Should manganese sulfate ever come into contact with these various incompatible substances either during use, transportation, storage, or disposal, violent and even explosive reactions are possible. Manganese occurs naturally in many minerals that are widely distributed in the earth's crust and, in trace amounts, is an essential element for both plants and animals. The wide variety of possible manganese compounds may enter the environment from natural and industrial sources.

Acute Ecological Effects

Acute (short-term) toxic effects may include the death of animals, birds, or fish and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to manganese.

Manganese and its compounds have moderate acute toxicity to aquatic life. While manganese is considered essential for plant and animal life, insufficient data are available on the acute effects of excessive manganese sulfate contamination on plants, birds, or land animals.

Chronic Ecological Effects

Chronic (long-term) toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed

animals. These effects can be seen long after first exposure(s) to toxic chemicals.

Manganese and its compounds have moderate chronic toxicity to aquatic life. Manganese is considered essential for plant and animal life. However, insufficient data are available on the chronic effects of excessive manganese contamination on plants, birds, or land animals.

Water Solubility

Manganese and its compounds vary in their solubility in water from very soluble to nearly insoluble. In water, manganese reacts and decomposes to form explosive hydrogen gas. Manganese sulfate easily dissolves in hot (boiling) water and becomes highly mobile.

Persistence in the Environment

Manganese and its compounds are highly persistent in water, with a half-life greater than 200 days. The half-life of a pollutant is the amount of time it takes for one half of the chemical to be degraded. Manganese is also naturally present in terrestrial soils and aquatic sediments.

Bioaccumulation in Aquatic Organisms

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans.

The concentration of manganese found in fish tissues is expected to be about the same as the average concentration of manganese found in the water from which the fish was taken.

Recommended Risk-Reduction Measures

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in a leak or spill of manganese sulfate dusts or powders into the environment. The correct use of labeling on all containers, trucks, and rail cars will enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of manganese sulfate should be segregated from incompatible chemicals to minimize the risk of cross-contamination or contact. Care should be taken to prevent physical damage to storage contain-

ers. Also, dusty conditions must be avoided in storage and use areas.

If a spill or leak to the environment has occurred, fire department, emergency response and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those trained in proper spill containment procedures. Contaminated soils should be removed for decontamination and replaced with clean soil. If manganese sulfate should contact the water table, aquifer, or navigable waterway, response activities should be prompt. The local and/or state emergency response authorities may require notification. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of manganese sulfate.

If manganese sulfate is spilled or leaked, the following specific steps are recommended:

- Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened for normal work.
- Ventilate area of spill or leak.
- Collect powdered materials in the safest manner possible and deposit in sealed containers. Recommend using a vacuum equipped with a high-efficiency particulate air (HEPA) filter. Do not dry sweep (generates airborne dusts). Absorb solution spills with vermiculite or other material, collect, and place in sealed drum for disposal.
- It may be necessary to dispose of manganese sulfate as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving manganese sulfate can present a significant threat to business operations. The loss or damage of equipment or facilities can significantly affect fiscal viability. Lawsuits that may result from personnel injury/death, public exposures, and/or environmental contamination will also require a serious expenditure of resources. Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business. Always remember that anytime the terms "cancer," "carcinogen," or

"reproductive hazard" are used, public emotion, hysteria, and ignorance can run equally high. This must be carefully considered whenever developing public relations policies.

Recommended Risk-Reduction Measures

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures for responding to chemical incidents. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

MANGANESE TETROXIDE

CAS: 1317-35-7

**IDENTIFICATION AND TYPICAL USES**

Manganese tetroxide appears as a black or brownish-black fine powder with no detectable odor. Manganese tetroxide is created whenever manganese oxides are heated to high temperatures, as in welding, cutting, brazing, or other hot work, especially involving the release of ferromanganese fumes. There is no commercial use for manganese tetroxide. It is simply a hazardous by-product of other processes.

RISK ASSESSMENT: HEALTH**General Assessment**

Even though manganese is an essential mineral in human nutrition, it can also be toxic by *inhalation* of its fumes and/or by *ingestion* of the powders and dusts. While manganese has been shown to cause tumors in experimental test animals with mutation data also reported, the exact nature of manganese tetroxide's human carcinogenic properties is unknown. Experimental reproductive effects have been documented.

Inhalation of manganese tetroxide dusts can irritate the respiratory tract with progression to lung damage, pleuritis, bronchitis, and possible respiratory infections and fatal pneumonia. The fumes can cause acute or chronic poisoning with primary effects on the immune system characterized by symptoms of metal fume fever. These can include fever, chills, general weakness, body aches, frontal headache, blurred vision, back pain and stiffness, muscular cramps, shallow and labored respiration, dryness in the mouth and throat with intense thirst, dry cough, metallic taste, and tightness in the chest occurring several hours after exposure. Lung irritation can become severe with inflammation causing manganese tetroxide pneumonitis. Other effects of central nervous system depression include headache, insomnia, changes in personality, emotions, and attitude, irritability, inappropriate laughter or crying, hallucinations, effects on vision (double vision, blurred vision), uncontrolled impulse

behavior, euphoria, salivation, trembling, staggering gait, and symptoms normally associated with Parkinson's disease.

☠ Acute Health Effects

The following acute (short-term) health effects may occur immediately or shortly after human exposure to manganese tetroxide:

- Skin:** Manganese tetroxide particles can become embedded under the skin causing localized inflammation and redness.
- Eye:** Irritation to the eye and associated tissues. Effects appear to be minor and temporary.
- Lung:** Irritation of the mucosa of the eyes, nose, throat, and respiratory tract.
- CNS:** Breathing heated fumes can cause metal fume fever with specific action on the central nervous system.

☘ Chronic Health Effects

The following chronic (long-term) health effects may occur at some time after exposure to manganese tetroxide and can last for months or even years:

Cancer Hazards: According to the references, manganese has been shown to cause tumors in test animals. There are no reports of the specific carcinogenic properties of manganese tetroxide.

Reproductive Hazard: According to the references, there is some limited evidence that chronic overexposure to manganese tetroxide may cause adverse reproductive effects in test animals.

Other Chronic Effects: Prolonged or repeated exposure can damage the central nervous system and cause impaired mental function and degenerative brain changes with emotional instability, and changes in motor control, vision, and other body functions.

🛡 Recommended Risk-Reduction Measures

While manganese is an essential mineral in human nutrition, the base mineral as well as many of its compounds (including in the tetroxide) can be extremely toxic under certain exposure conditions. Personnel should, therefore, avoid direct occupational contact with manganese tetroxide. If a less toxic material or compound cannot be substituted for manganese tetroxide, then *engineering controls* are the most effective method of reducing exposures. The best protection is to enclose operations and/or provide local exhaust ventilation at the site of manganese tetroxide dust release. While not always operationally feasible, isolating operations can also reduce exposure. Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around manganese tetroxide. Manganese tetroxide is generated whenever manganese oxides are heated to high temperatures. Respiratory protection should be provided whenever welding, cutting, brazing, or other hot work occurs. The exposure ceiling for manganese is relatively low ($5\text{mg}/\text{m}^3$) and difficult to accurately monitor. For low or transient exposures, a chemical cartridge respirator equipped with a high-efficiency particulate air (HEPA) filter and a dust/mist pre-filter may provide adequate respiratory protection. Better protection is obtained using a supplied-air respirator operated in continuous flow mode or a self-contained breathing apparatus (SCBA) with full facepiece operated in pressure demand. If a full facepiece is not available, then chemical/dust goggles should be worn to protect the eyes. A face shield and protective apron should also be worn. To prevent hand and skin exposures, gloves should be used. Glove manufacturers should be contacted *before* selections are made.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with manganese tetroxide.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where manganese tetroxide is used or stored.

Before beginning employment working with manganese tetroxide, and at regular intervals thereafter (e.g., annually), those personnel with frequent or potentially high exposures should be provided the following recommended medical tests:

- Complete blood count (establish baseline).
- Complete examination of the nervous system.
- Lung function tests (may be normal if the person is not having an attack at the time of the test)
- Kidney function tests.

If symptoms develop or overexposure is suspected, consider the following additional tests:

- Complete blood count (compare to baseline).
- Consider chest X-ray after acute overexposure.
- Lung function tests.

Any evaluation should include a careful history of past and present symptoms with an examination. Medical tests that simply look for existing damage are not a substitute for controlling exposures. Also, since smoking causes heart disease, lung cancer, emphysema, and other respiratory diseases, smokers exposed to manganese tetroxide may experience symptoms more rapidly than non-smokers under the same conditions of exposure. Prudent risk management requires careful consideration of *all* factors which may be causing exposure symptoms in the workplace.

Other methods to reduce exposure include:

- Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not used, respiratory protection should be mandatory.
- Always ensure that proper protective clothing is worn when using chemical substances. Proper maintenance and care of protective equipment is essential to its proper function.
- Wash thoroughly immediately after exposure to manganese tetroxide and at the end of the work shift or before eating, drinking, or smoking.
- Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of manganese tetroxide should be communicated to all exposed and potentially exposed workers.
- Eye wash stations should be provided in the immediate work area for emergency use. If there is a possibility of skin exposure to manganese tetroxide, emergency shower facilities should be provided.
- Workers whose clothing has been contaminated by manganese tetroxide should change into clean

clothes before leaving work. Never wear contaminated clothing home where family members can be exposed. Contaminated work clothing should be laundered only by individuals who have been informed of the hazards of exposure to manganese tetroxide.

RISK ASSESSMENT: ENVIRONMENT

General Assessment

As a naturally occurring mineral, manganese poses very little threat to the environment. However, accidental spills or releases to the environment can occur during transportation, storage, disposal, or destruction of manganese tetroxide. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance. Accidental spills, large or small, where manganese tetroxide contacts incompatible commodities can result in release of toxic products (depending upon conditions of spill), and possible contamination of the surrounding environmental mediums (water, soil, and air).

Manganese tetroxide is considered a noncombustible solid. It is incompatible with strong reducing agents, acids, and bases. Extreme caution is always required in handling, storage, transportation, and disposal of manganese tetroxide. Its reactive characteristics also require special consideration during any emergency situation involving a leak or spill of manganese tetroxide powder or dust. Should manganese tetroxide ever come into contact with incompatible substances either during use, transportation, storage, or disposal, violent and even explosive reactions are possible.

Manganese occurs naturally in many minerals that are widely distributed in the earth's crust and, in trace amounts, is an essential element for both plants and animals. The wide variety of possible manganese compounds may enter the environment from natural and industrial sources.

Acute Ecological Effects

Acute (short-term) toxic effects may include the death of animals, birds, or fish and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to manganese tetroxide.

Manganese and its compounds have moderate acute toxicity to aquatic life. While manganese tetroxide is considered essential for plant and animal life, insufficient data are available on the acute effects

of excessive manganese tetroxide contamination on the other ecosystems (plants, birds, or land animals).

Chronic Ecological Effects

Chronic (long-term) toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals.

Manganese and its compounds have moderate chronic toxicity to aquatic life. Manganese tetroxide is considered essential for plant and animal life. However, insufficient data are available on the chronic effects of excessive manganese tetroxide contamination on the other ecosystems (plants, birds, or land animals).

Water Solubility

Manganese and its compounds vary in their solubility in water from very soluble to nearly insoluble.

Persistence in the Environment

Manganese and its compounds are highly persistent in water, with a half-life greater than 200 days. The half-life of a pollutant is the amount of time it takes for one half of the chemical to be degraded.

Bioaccumulation in Aquatic Organisms

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans.

The concentration of manganese tetroxide found in fish tissues is expected to be about the same as the average concentration of manganese tetroxide in the water from which the fish was taken.

Recommended Risk-Reduction Measures

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in a leak or spill of manganese tetroxide dusts or powders into the environment. The correct use of labeling on all containers, trucks, and rail cars will enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of manganese tetroxide should be segregated from incompatible chemicals to minimize the risk of cross-contamination or contact. Care should be taken to prevent physical damage to storage containers. Also, dusty conditions must be avoided in storage and use areas.

If a spill or leak to the environment has occurred, fire department, emergency response and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those trained in proper spill containment procedures. Contaminated soils should be removed for decontamination and replaced with clean soil. If manganese tetroxide should contact the water table, aquifer, or navigable waterway, response actions should be prompt. The local and/or state emergency response authorities may require notification. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of manganese tetroxide.

If manganese tetroxide is spilled or leaked, the following specific steps are recommended:

- Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened for normal work.
- Remove ignition sources and ventilate area.
- Cover spilled materials with clean, moist sand. Mix and collect powdered materials in the safest manner possible and deposit in sealed containers. Recommend using a vacuum equipped with a high-efficiency particulate air (HEPA) filter on residues. Do NOT dry sweep (generates dusts).
- It may be necessary to dispose of manganese tetroxide as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving manganese tetroxide can present a significant threat to business operations. The loss or damage of equipment or facilities can significantly affect fiscal viability. Lawsuits that may result from personnel injury/death, public exposures, and/or environmental contamination will also require a serious expenditure of resources. Media attention surrounding an injury, death, or environmental dam-

age can also result in a loss of profits and loss of current as well as future business. Always remember that anytime the term "reproductive hazard" is used, public hysteria, emotion, and ignorance can run equally high. This should be carefully considered during the development of public relations policies.

Recommended Risk-Reduction Measures

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures for responding to chemical incidents. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

| Medical Conditions Generally Aggravated by Exposure Mercury-sensitive people, existing dental and oral problems, kidney disease, respiratory problems, and central nervous system disorders may be aggravated by exposure to mercuric acetate. | | | | |
| Emergency and First-aid Procedures | | | | |
| Eye contact: Flush immediately with water for 15 minutes (minimum); seek medical attention. Skin contact: Remove all contaminated clothing. Immediately wash area with large amounts of soap and water. For inhalation: Remove the person from exposure. Provide respiratory assistance and CPR. Transfer to medical facility. Observe for 48 hours for lung effects. If swallowed: Provide breathing assistance if necessary. Never attempt to give a convulsing or unconscious person anything by mouth. If victim is conscious, give 1-2 glasses of water to dilute and induce vomiting. | | | | |
| SECTION VII - PRECAUTIONS FOR SAFE HANDLING AND USE | | | | |
| Steps to be Taken in Case Material is Released or Spilled | | | | |
| Collect powdered material and deposit in sealed drum. Keep those not involved in cleanup from entering area. Do NOT dry sweep (creates airborne dusts). Use a vacuum equipped with a (HEPA) filter. Absorb solution spills in vermiculite or other materials. | | | | |
| Preferred Waste Disposal Method | | | | |
| No Citation. | | | | |
| Precautions to be Taken in Handling and Storage | | | | |
| Store in tightly closed containers in cool, well-ventilated area. Sources of ignition are prohibited where mercuric acetate is stored. Keep away from light. | | | | |
| Other Precautions and Warnings | | | | |
| Outside or detached storage facility is recommended. Protect containers from physical damage. | | | | |
| SECTION VIII - CONTROL MEASURES AND PERSONAL PROTECTIVE EQUIPMENT | | | | |
| Respiratory Protection (<i>specify type</i>) | | | | |
| Exposure levels are low and difficult to monitor. For best protection, use a supplied-air respirator with a full facepiece or a self-contained breathing apparatus (SCBA) operated in positive pressure mode. | | | | |
| Ventilation | | | | |
| Local exhaust or general mechanical systems recommended. | | | | |
| Protective Gloves | Eye Protection | Other Protective Clothing | | |
| Impervious Material | Chemical/Dust Goggles or Face Mask | Protective Suit or Clothing | | |
| Work/Hygiene Practices | | | | |
| Always wash hands thoroughly after using chemical; never bring food, drink, or smoking materials into vicinity of chemicals. Skin contact must be avoided. | | | | |

MERCURIC ACETATE

CAS: 1600-27-7

**IDENTIFICATION AND TYPICAL USES**

Mercuric acetate appears as a white crystalline, sugar or sand-like solid with no detectable odor. It is used in the manufacture of other chemicals and pharmaceuticals.

RISK ASSESSMENT: HEALTH**General Assessment**

Mercuric acetate is a toxic human poison by three routes of exposure: *inhalation*, *ingestion*, and *dermal absorption*. Mercury accumulates in the body with each exposure. While it is not currently listed as a carcinogenic compound, mutation data have been reported for many mercury compounds. Organic mercury compounds (those that contain carbon), such as mercuric acetate have caused adverse reproductive effects (miscarriages and/or fetal damage) in test animals.

Symptoms of exposure by inhalation of mercury acetate vapors are headache, dyspnea, cough, chills, fever, pneumonitis, and delayed pulmonary edema (fluid in the lungs), which can be fatal. Symptoms of pulmonary edema (cough, chest pain, congestion, nausea, dizziness) may be delayed up to 48 hours thereby creating a false sense of security with regard to health exposure risk.

Ingestion of mercury or its compounds causes abdominal pain, bloody diarrhea, gastrointestinal irritation, vomiting, and cardiac arrhythmia.

Repeated exposure from inhalation, absorption, and/or ingestion can cause central nervous system (CNS) effects including vertigo, anxiety, depression, ataxia, emotional instability, kidney injury, brain damage, tremors (the "shakes"), memory loss, metallic taste, discoloration of the skin, sore gums, personality changes, liver damage, loose teeth, necrosis of the

jaw, decreased urine excretion, visual disturbances, and possible development of dermatitis.

☠ Acute Health Effects

The following acute (short-term) health effects may occur immediately or shortly after exposure to mercuric acetate:

Skin: Irritation, rash, dermatitis, and possible redness and the appearance of small blisters. Dermal absorption can be quick and will cause toxic systemic effects.

Eye: Irritation, inflammation, watering, and swelling, burns, and tissue damage.

Lung: Inhalation of mercuric acetate dusts may cause irritation of the mucous membranes in the respiratory tract causing cough, phlegm, and lung tissue irritation. It can also lead to pneumonitis as well as pulmonary edema, which is a medical emergency and can be fatal.

☘ Chronic Health Effects

The following chronic (long-term) health effects may occur at some time after exposure to mercuric acetate and can last for months or even years:

Cancer Hazards: According to the information presented in the references, mercuric acetate has not been adequately tested for its ability to cause cancer in test animals. However, mutation (causes genetic changes) data have been documented and many scientists believe that such chemicals may pose a cancer risk in the long-term. More research is required.

Reproductive Hazards: According to information available in the references, organic mercury compounds (such as mercuric acetate) have been shown to adversely affect reproduction in humans and animals. They can cause the early termination of pregnancies (miscarriages) and may injure the fetus. Mercury may

also reduce fertility in both males and females. While inorganic mercury substances (those without carbon), have not specifically been shown to be human teratogens, they should still be handled with caution as they may cause reproductive problems in males and females.

Other Chronic Hazards: High or repeated exposure can cause kidney damage or mercury poisoning with symptoms of sore gums, "shakes" (especially noticeable in handwriting), irritability, increased saliva production, memory loss, extreme shyness, weakness, loss of teeth, poor appetite, and metallic taste. Serious personality changes and brain damage can occur, especially if exposure continues. Repeated skin contact may cause gray discoloration and a skin allergy may develop. If this happens, even small future exposures can cause rash. Repeated exposures may also cause reduced peripheral vision and brown staining of the eye. Mercury can accumulate in the body on prolonged exposure and it may take months or years for the body to dispose of excess mercury.

🕒 Recommended Risk-Reduction Measures

Personnel should avoid direct contact with mercuric acetate. Mercury is an extremely toxic, cumulative poison. If a less toxic chemical cannot be substituted for a hazardous material, then *engineering controls* are the most effective method of reducing exposures.

The best protection is to enclose operations and/or provide local exhaust ventilation at the site of chemical release. While not always operationally feasible, isolating operations can also reduce exposure. Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around mercuric acetate. Exposure levels for mercury are extremely low (0.05 mg/m^3) and difficult to monitor accurately. A full facepiece respirator with a high-efficiency particulate air (HEPA) filter equipped with a dust/mist/fume pre-filter may suffice. However, for the best protection use a supplied-air respirator with a full facepiece operated in positive pressure mode or an MSHA/NIOSH-approved self-contained breathing apparatus (SCBA) with full facepiece operated in pressure demand or other continuous flow mode. If a full facepiece is not available, then chemical/dust goggles should be worn to protect the eyes. Whenever a chemical dust hazard exists, a face shield and a protective apron should be worn. To prevent hand and skin exposures, impervious rubber gloves should be used. Glove manufacturers should be contacted and permeation studies obtained *before* final glove selections are made. Skin

contact must be prevented. Protective suits and clothing should be used.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with mercuric acetate dusts or solutions. All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where mercuric acetate is used or stored. Before first exposure and every six to twelve months thereafter, a complete medical history and examination is recommended, including the following:

- Examination of the nervous system (taking note of any problems with person's handwriting).
- Routine urinalysis and special urine test for mercury (should be less than 0.02 mg/liter).
- Eye examination.
- Lung function tests for frequent exposures.

If symptoms develop or overexposure is suspected, the above listed tests should be repeated, along with the following recommended tests:

- Consider nerve conduction tests.
- Urinary enzyme and neurological behavior tests.
- Serum mercury tests.
- Consider chest X-ray following acute overexposure (may be negative if taken immediately after exposure due to delayed onset of pulmonary edema).

Any evaluation should include a careful history of past and present symptoms with a medical examination. Medical tests that look for damage already done are not a substitute for controlling exposure. Also, since smoking can cause heart disease, emphysema, and a number of other respiratory disorders, smokers exposed to lung irritants such as mercuric acetate dusts and fumes may experience symptoms much more quickly than non-smokers under the same conditions of exposure. Prudent risk management requires proper consideration of *all* factors which may be causing the appearance of exposures symptoms in the work place.

Other methods to reduce exposure include:

- Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not

used, respiratory protection should be provided and its use mandatory.

- ☑ Always ensure that proper protective clothing is worn when using chemical substances and that personnel are trained in its use and care.
- ☑ Wash thoroughly immediately after exposure to mercuric acetate and at the end of the work shift or before eating, drinking, or smoking.
- ☑ Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of mercuric acetate should be communicated to all exposed and potentially exposed workers.
- ☑ Eye wash stations and emergency showers should be located in the immediate work area.
- ☑ Work clothing that has been contaminated with mercuric acetate should never be worn home where family members can be exposed as well. Contaminated clothing should be laundered at work or by an authorized service by personnel who have been trained in the hazards associated with exposure to mercuric acetate.
- ☑ The drug n-acetyl penicillamine (NAP) has been used to treat mercury poisoning, with mixed success.
- ☑ Specific engineering controls are recommended for mercury by NIOSH. Refer to NIOSH Criteria Document, "Inorganic Mercury" (Publication Number 73-11024).

RISK ASSESSMENT: ENVIRONMENT

General Assessment

The environment is at risk of exposure during transportation, storage, disposal, or destruction of mercuric acetate. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance. Accidental spills, large or small, can result in fire, explosion, and possible contamination of the surrounding environmental mediums (water, soil, and air).

Mercuric acetate is incompatible with many common oxidizers and acids. Reactions can be vigorous and violent. It is also sensitive to heat and light. In a fire, mercuric acetate will emit toxic and poisonous mercury fumes. These characteristics require special consideration during any emergency situation involving a leak or spill of mercuric acetate.

Elemental mercury is a heavy and relatively inert liquid which is oxidized to inorganic mercury (II) under natural conditions. Mercury (II) may combine with an organic fraction to form methyl mercury. Both mercury (II) and methyl mercury can cause environmental contamination. Mercury (II) may enter the environment in industrial or municipal waste treatment discharges, from previously contaminated sediments, and from the weathering of natural rocks. Bacteria may then convert it to methyl mercury. The concentration of mercury (II) in water may be elevated with acid rain due to the scouring of mercury from the air and increased partitioning from the sediment into the water.

☠ Acute Ecological Effects

Acute (short-term) toxic effects may include the death of animals, birds, or fish and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to mercuric acetate. Mercury (II) and methyl mercury have high acute toxicity to aquatic life. Insufficient data are available to evaluate the short-term effects of mercury (II) and methyl mercury exposure to plants, birds or terrestrial animals.

🕒 Chronic Ecological Effects

Chronic (long-term) toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals. Mercury (II) and methyl mercury have high chronic toxicity to aquatic life. Eating fish contaminated with mercury residues has caused secondary poisoning in humans. Birds or land animals similarly exposed to mercury and its compounds could also be subject to such effects. Insufficient data are available to evaluate the long-term effects of mercuric acetate exposure to plants.

💧 Water Solubility

Mercuric acetate is soluble in water. Concentrations of 1000 milligrams or more will mix with a liter of water. Mercury is insoluble in the aquatic environment.

🕒 Persistence in the Environment

Mercury is highly persistent in water, with a half-life greater than 200 days. The half-life of a pollutant is the amount of time it takes for one half of the chemi-

Risk Management for Hazardous Chemicals

cal to be degraded. When released into water, microorganisms convert mercuric salts into methyl mercury which is rapidly taken up by algae and enters the food chain. It concentrates in the edible tissues of fish and, eventually, can cause human poisoning as well.

🌊 Bioaccumulation in Aquatic Organisms

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans. The concentration of mercury and methyl mercury found in fish tissues is expected to be considerably higher than the average concentration in the water from which the fish was taken.

🕒 *Recommended Risk-Reduction Measures*

Proper training of all transporters will reduce the likelihood of a mishap or accidents resulting in a leak or spill to the environment. Proper labeling on all containers, trucks, and rail cars will enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

If a spill or leak to the environment has occurred, fire department, emergency response and/or hazardous materials spill personnel should be notified immediately. Do not dry sweep. When vacuuming, a high efficiency particulate air (HEPA) filter should be used, not a standard shop vacuum. Deposit collected materials in sealed drums for disposal. Cleanup should be attempted only by those trained in proper spill containment procedures. Contaminated soils may need to be removed and replaced with clean soil. If mercuric acetate should contact the water table, aquifer, or navigable waterway, time is of the essence. Mercuric acetate is soluble in water and total containment and remediation may not be possible. When such spills occur, the local and/or state emergency response authorities should be notified. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of mercuric acetate. If mercuric acetate is spilled or leaked, the following specific steps are recommended:

- ☑ Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened for normal work.

- ☑ Ventilate area of spill or leak and remove all ignition sources.
- ☑ Collect powdered materials in safe manner and place in sealed drums for disposal. Do NOT dry sweep; use HEPA vacuum instead.
- ☑ It may be necessary to dispose of mercuric acetate as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving mercuric acetate can present a significant threat to business operations. The loss or damage of equipment or facilities can significantly affect fiscal viability. Lawsuits that may result from personnel injury/death, public exposures, and/or environmental contamination will also require a serious expenditure of resources. Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business. Always remember that anytime the term "reproductive hazard" is used, public emotion, hysteria, and ignorance can run equally high. This must be properly considered whenever developing public relations policies.

🕒 *Recommended Risk-Reduction Measures*

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of such procedures dealing with safety or emergency response. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

MERCURIC CHLORIDEHgCl₂

CAS: 7487-94-7

**IDENTIFICATION AND TYPICAL USES**

Mercuric chloride appears as a white crystalline solid with no detectable odor. It is used in the manufacture of calomel and other mercury compounds, as a disinfectant, in organic synthesis, as an analytical reagent, in metallurgy, in tanning, as a catalyst for vinyl chloride, in sterilizing seed potatoes, as a fungicide, insecticide, as a wood preservative, in embalming fluids, in textile printing, dry batteries, photography, process engraving, and lithography.

RISK ASSESSMENT: HEALTH***General Assessment***

Mercuric chloride is a toxic human poison by three routes of exposure: *inhalation*, *ingestion*, and *dermal absorption*. Mercury accumulates in the body with each exposure. While it is not currently listed as a carcinogenic compound, human mutation data have been reported for inorganic mercury compounds. Mercuric chloride has caused adverse human reproductive effects (miscarriages and/or fetal damage).

Symptoms of exposure by inhalation of mercury chloride vapors include headache, dyspnea, cough, chills, fever, pneumonitis, and delayed pulmonary edema (fluid in the lungs), which can be fatal. Symptoms of pulmonary edema may be delayed up to 48 hours thereby creating a false sense of security with regard to health exposure risk.

Ingestion causes abdominal pain, bloody diarrhea, gastrointestinal irritation, vomiting, and cardiac arrhythmia. Repeated exposure from inhalation, absorption, and/or ingestion can cause CNS effects including vertigo, anxiety, depression, ataxia, emotional instability, kidney injury, brain damage, tremors (the "shakes"), sore gums, personality changes, liver damage, loose teeth, necrosis of the jaw, decreased urine excretion, visual disturbances, and dermatitis.

☠ *Acute Health Effects*

The following acute (short-term) health effects may occur immediately or shortly after exposure to mercuric chloride:

- Skin: Irritation, rash, dermatitis, and possible redness and the appearance of small blisters. Dermal absorption can be quick and will cause toxic systemic effects.
- Eye: Irritation, inflammation, watering, and swelling.
- Lung: Inhalation of mercuric chloride dusts may cause irritation of the mucous membranes in the respiratory tract causing cough, phlegm, and lung tissue irritation. It can also lead to pneumonitis as well as pulmonary edema, which can be fatal.

☠ *Chronic Health Effects*

The following chronic (long-term) health effects may occur at some time after exposure to mercuric chloride and can last for months or even years:

Cancer Hazards: According to the information presented in the references, mercuric chloride has not been adequately tested for its ability to cause cancer in test animals. However, human mutation (causes genetic changes) data have been documented and many scientists believe that such chemicals may pose a cancer risk in the long-term.

Reproductive Hazards: According to information available in the references, mercuric chloride has been shown to adversely affect reproduction in humans and animals. It causes the early termination of pregnancies (miscarriages) and may injure the fetus. It may also reduce fertility in both males and females. While inorganic mercury substances (those without carbon), such as mercury chloride, have not specifically been shown to be human teratogens, they should still be

handled with caution as they may cause reproductive problems in males and females.

Other Chronic Hazards: High or repeated exposure can cause kidney damage or mercury poisoning with symptoms of sore gums, "shakes" (especially noticeable in handwriting), irritability, increased saliva production, memory loss, extreme shyness, weakness, loss of teeth, poor appetite, and metallic taste. Serious personality changes and brain damage can occur, especially if exposure continues. Repeated skin contact may cause gray discoloration and a skin allergy may develop. If this happens, even small future exposures can cause rash. Repeated exposures may also cause reduced peripheral vision and brown staining of the eye. Mercury can accumulate in the body on prolonged exposure and it may take months or years for the body to dispose of excess mercury.

🔑 **Recommended Risk-Reduction Measures**

Personnel should avoid direct contact with mercuric chloride. It is an extremely toxic, cumulative poison. If a less toxic chemical cannot be substituted for a hazardous material, then *engineering controls* are the most effective method of reducing exposures.

The best protection is to enclose operations and/or provide local exhaust ventilation at the site of chemical release. While not always operationally feasible, isolating operations can also reduce exposure. Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around mercuric chloride. Exposure levels for mercury are extremely low (0.05 mg/m^3) and difficult to monitor accurately. A full facepiece respirator with a high-efficiency particulate air (HEPA) filter equipped with a dust/mist/fume pre-filter may suffice. However, for the best protection use a supplied-air respirator with a full facepiece operated in positive pressure mode or an MSHA/NIOSH-approved self-contained breathing apparatus (SCBA) with full facepiece operated in pressure demand or other continuous flow mode. If a full facepiece is not available, then chemical/dust goggles should be worn to protect the eyes. Whenever a chemical dust hazard exists, a face shield and a protective apron should be worn. To prevent hand and skin exposures, impervious rubber gloves should be used. Glove manufacturers should be contacted and permeation studies obtained *before* final glove selections are made. Skin contact must be prevented. Protective suits and clothing should be used.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with mercuric chloride dusts or solutions.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where mercuric chloride is used or stored. Before first exposure and every six to twelve months thereafter, a complete medical history and examination is recommended, including the following:

- Examination of the nervous system (taking note of any problems with person's handwriting).
- Routine urinalysis and special urine test for mercury (should be less than 0.02 mg/liter).
- Eye examination.
- Consider lung function tests for persons with frequent exposure.

If symptoms develop or overexposure is suspected, the above listed tests should be repeated, along with the following recommended tests:

- Consider nerve conduction tests.
- Urinary enzyme and neurological behavior tests.
- Consider chest X-ray following acute overexposure (may be negative if taken immediately after exposure due to delayed onset of pulmonary edema).

Any evaluation should include a careful history of past and present symptoms with a medical examination. Medical tests that look for damage already done are not a substitute for controlling exposure. Also, since smoking can cause heart disease, emphysema, and a number of other respiratory disorders, smokers exposed to lung irritants such as mercuric chloride dusts and fumes may experience symptoms much more quickly than non-smokers under the same conditions of exposure. Prudent risk management requires proper consideration of *all* factors which may be causing the appearance of exposures symptoms in the work place.

Other methods to reduce exposure include:

- Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not used, respiratory protection should be provided and its use mandatory.

- ☑ Always ensure that proper protective clothing is worn when using chemical substances and that personnel are trained in its use and care.
- ☑ Wash thoroughly immediately after exposure to mercuric chloride and at the end of the work shift or before eating, drinking, or smoking.
- ☑ Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of mercuric chloride should be communicated to all exposed and potentially exposed workers.
- ☑ Eye wash stations and emergency showers should be located in the immediate work area.
- ☑ Work clothing that has been contaminated with mercuric chloride should never be worn home where family members can be exposed as well. Contaminated clothing should be laundered at work or by an authorized service by personnel who have been trained in the hazards associated with exposure to mercuric chloride.
- ☑ Specific engineering controls are recommended for mercury by NIOSH. Refer to NIOSH Criteria Document, "Inorganic Mercury" (Publication Number 73-11024).

RISK ASSESSMENT: ENVIRONMENT

General Assessment

The environment is at risk of exposure during transportation, storage, disposal, or destruction of mercuric chloride. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance. Accidental spills, large or small, can result in fire, explosion, and possible contamination of the surrounding environmental mediums (water, soil, and air).

Mercuric chloride is incompatible with many compounds, including formates, sulfites, phosphates, albumin, ammonia, other metals, even vegetable astringents. Reactions can be vigorous and violent. In a fire, mercuric chloride will emit toxic and poisonous mercury fumes. These characteristics require special consideration during any emergency situation involving a leak or spill of mercuric chloride.

Elemental mercury is a heavy and relatively inert liquid which is oxidized to inorganic mercury (II) under natural conditions. Mercury (II) may combine with an organic fraction to form methyl mercury.

Both mercury (II) and methyl mercury can cause environmental contamination. Mercury (II) may enter the environment in industrial or municipal waste treatment discharges, from previously contaminated sediments, and from the weathering of natural rocks. Bacteria may then convert it to methyl mercury. The concentration of mercury (II) in water may be elevated with acid rain due to the scouring of mercury from the air and increased partitioning from the sediment into the water.

☠ Acute Ecological Effects

Acute (short-term) toxic effects may include the death of animals, birds, or fish and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to mercuric chloride.

Mercury (II) and methyl mercury have high acute toxicity to aquatic life. Insufficient data are available to evaluate the short-term effects of mercury (II) and methyl mercury exposure to plants, birds or terrestrial animals.

⚙️ Chronic Ecological Effects

Chronic (long-term) toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals.

Mercury (II) and methyl mercury have high chronic toxicity to aquatic life. Eating fish contaminated with mercury residues has caused secondary poisoning in humans. Birds or land animals similarly exposed to mercury and its compounds could also be subject to such effects. Insufficient data are available to evaluate the long-term effects of mercuric chloride exposure to plants.

💧 Water Solubility

Mercuric chloride is soluble in water. Concentrations of 1000 milligrams or more will mix with a liter of water. Mercury itself is insoluble in the water.

🕒 Persistence in the Environment

Mercury is highly persistent in water, with a half-life greater than 200 days. The half-life of a pollutant is the amount of time it takes for one half of the chemical to be degraded. When released into water, microorganisms convert mercuric salts into methyl mercury which is rapidly taken up by algae and enters the food

chain. It concentrates in the edible tissues of fish and, eventually, can cause human poisoning as well.

🌊 Bioaccumulation in Aquatic Organisms

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans. The concentration of mercury and methyl mercury found in fish tissues is expected to be considerably higher than the average concentration in the water from which the fish was taken.

🕒 Recommended Risk-Reduction Measures

Proper training of all transporters will reduce the likelihood of a mishap or accidents resulting in a leak or spill to the environment. Proper labeling on all containers, trucks, and rail cars will enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

If a spill or leak to the environment has occurred, fire department, emergency response and/or hazardous materials spill personnel should be notified immediately. Do not dry sweep. When vacuuming, a high efficiency particulate air (HEPA) filter should be used, not a standard shop vacuum. Deposit collected materials in sealed drums for disposal. Cleanup should be attempted only by those trained in proper spill containment procedures. Contaminated soils may need to be removed and replaced with clean soil. If mercuric chloride should contact the water table, aquifer, or navigable waterway, time is of the essence. Mercuric chloride is soluble in water and total containment and remediation may not be possible. When such spills occur, the local and/or state emergency response authorities should be notified. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of mercuric chloride. If mercuric chloride is spilled or leaked, the following specific steps are recommended:

- Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened for normal work.
- Ventilate area of spill or leak and remove all ignition sources.

- Collect powdered materials in most convenient and safe manner possible and place in sealed drums for disposal. Do NOT dry sweep; use HEPA vacuum instead.
- It may be necessary to dispose of mercuric chloride as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving mercuric chloride can present a significant threat to business operations. The loss or damage of equipment or facilities can significantly affect fiscal viability. Lawsuits that may result from personnel injury/death, public exposures, and/or environmental contamination will also require a serious expenditure of resources. Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business. Always remember that anytime the term "reproductive hazard" is used, public emotion, hysteria, and ignorance can run equally high. This must be properly considered whenever developing public relations policies.

🕒 Recommended Risk-Reduction Measures

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of such procedures dealing with safety or emergency response. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

MERCURIC CYANIDEHg(CN)₂

CAS: 592-04-1

**IDENTIFICATION AND TYPICAL USES**

Mercuric cyanide appears as a colorless or white crystalline, transparent solid (prisms) with no detectable odor. It is used in the manufacture of medicines (an antiseptic), in germicidal soaps, in manufacturing of cyanogen gas, and in photography.

RISK ASSESSMENT: HEALTH***General Assessment***

Mercuric cyanide is a toxic human poison by three routes of exposure: *inhalation*, *ingestion*, and dermal *absorption*. Mercury accumulates in the body with each exposure and overexposures to cyanide compounds can cause sudden death. While mercury is not currently listed as a carcinogenic compound, mutation data have been reported for many mercury compounds. Organic mercury compounds (those that contain carbon), such as mercuric cyanide, have caused adverse reproductive effects (miscarriages and/or fetal damage) in test animals.

Symptoms of exposure by all inhalation of mercury cyanide vapors can include headache, dyspnea, cough, chills, fever, and pneumonitis. Cyanide causes bronchial irritation with cough and phlegm, and/or lung tissue irritation.

Ingestion of mercury or its compounds causes abdominal pain, bloody diarrhea, gastrointestinal irritation, vomiting, and cardiac arrhythmia.

Repeated exposure from inhalation, absorption, and/or ingestion of mercuric cyanide can cause central nervous system (CNS) effects due to both the cyanide and the mercury base. These include vertigo, anxiety, depression, ataxia, emotional instability, kidney injury, brain damage, tremors (the "shakes"), memory loss, metallic taste, discoloration of the skin, sore gums, personality changes, liver damage, loose teeth,

decreased urine excretion, visual disturbances, and dermatitis.

☠ *Acute Health Effects*

The following acute (short-term) health effects may occur immediately or shortly after exposure to mercuric cyanide:

Skin: Irritation, rash, dermatitis, and possible redness and the appearance of small blisters. Dermal absorption can be quick and will cause toxic systemic effects.

Eye: Irritation, inflammation, watering, and swelling, burns, and tissue damage.

Lung: Inhalation of mercuric cyanide causes irritation of the mucosa in the respiratory tract causing cough, phlegm, and lung tissue irritation.

☠* *Chronic Health Effects*

The following chronic (long-term) health effects may occur at some time after exposure to mercuric cyanide and can last for months or even years:

Cancer Hazards: According to the information presented in the references, mercuric cyanide has not been adequately tested for its ability to cause cancer in test animals. However, mutation (causes genetic changes) data have been documented and many scientists believe that such chemicals may pose a cancer risk in the long-term. More research is required.

Reproductive Hazards: According to information available in the references, organic mercury compounds (such as mercuric cyanide) have been shown to adversely affect reproduction in humans and animals. They can cause the early termination of pregnancies (miscarriages) and may injure the fetus. Mercury may also reduce fertility in both males and females. While inorganic mercury substances (those

without carbon), have not specifically been shown to be human teratogens, they should still be handled with caution as they may cause reproductive problems in males and females.

Other Chronic Hazards: High or repeated exposure can cause kidney damage or mercury poisoning with symptoms of sore gums, "shakes" (especially noticeable in handwriting), irritability, increased saliva production, memory loss, extreme shyness, weakness, loss of teeth, poor appetite, and metallic taste. Serious personality changes and brain damage can occur, especially if exposure continues. Repeated skin contact may cause gray discoloration and a skin allergy may develop. If this happens, even small future exposures can cause rash. Repeated exposures may also cause reduced peripheral vision and brown staining of the eye. Mercury can accumulate in the body on prolonged exposure and it may take months or years for the body to dispose of excess mercury.

🕒 **Recommended Risk-Reduction Measures**

Personnel should avoid direct contact with mercuric cyanide. Mercury is an extremely toxic, cumulative poison. If a less toxic chemical cannot be substituted for a hazardous material, then *engineering controls* are the most effective method of reducing exposures.

The best protection is to enclose operations and/or provide local exhaust ventilation at the site of chemical release. While not always operationally feasible, isolating operations can also reduce exposure. Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around mercuric cyanide. Exposure levels for mercury are extremely low (0.05 mg/m^3) and difficult to monitor accurately. A full facepiece respirator with a high efficiency particulate air (HEPA) filter equipped with a dust/mist/fume pre-filter may suffice. However, for the best protection use a supplied-air respirator with a full facepiece operated in positive pressure mode or an MSHA/NIOSH-approved self-contained breathing apparatus (SCBA) with full facepiece operated in pressure demand or other continuous flow mode. If a full facepiece is not available, then chemical/dust goggles should be worn to protect the eyes. Whenever a chemical dust hazard exists, a face shield and a protective apron should be worn. To prevent hand and skin exposures, impervious rubber gloves should be used. Glove manufacturers should be contacted and permeation studies obtained *before* final glove selections are made. Skin contact must be prevented. Protective suits and clothing should be used.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with mercuric cyanide dusts or solutions. All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where mercuric cyanide is used or stored. Before first exposure and every six to twelve months thereafter, a complete medical history and examination is recommended, including the following:

- ☑ Examination of the nervous system (taking note of any problems with person's handwriting).
- ☑ Routine urinalysis and special urine test for mercury (should be less than 0.02 mg/liter).
- ☑ Eye examination.
- ☑ Lung function tests for frequent exposures.

If symptoms develop or overexposure is suspected, the above listed tests should be repeated, along with the following recommended tests:

- ☑ Consider nerve conduction tests.
- ☑ Urinary enzyme and neurological behavior tests.
- ☑ Serum mercury tests.

Any evaluation should include a careful history of past and present symptoms with a medical examination. Medical tests that look for damage already done are not a substitute for controlling exposure. Also, since smoking can cause heart disease, emphysema, and a number of other respiratory disorders, smokers exposed to lung irritants such as mercuric cyanide dusts and fumes may experience symptoms much more quickly than non-smokers under the same conditions of exposure. Other mixed exposures occur when personnel use creams to whiten or bleach the skin that contain mercury. If so, their use increases exposure risk. Persons who are allergic to mercury may react to Mercurochrome or Merthiolate, which also contain mercury. Prudent risk management requires proper consideration of *all* factors which may be causing the appearance of exposures symptoms in the work place.

Other methods to reduce exposure include:

- ☑ Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not used, respiratory protection should be mandatory.

- ☑ Always ensure that proper protective clothing is worn when using chemical substances.
- ☑ Wash thoroughly immediately after exposure to mercuric cyanide and at the end of the work shift or before eating, drinking, or smoking.
- ☑ Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of mercuric cyanide should be communicated to all exposed and potentially exposed workers.
- ☑ Eye wash stations and emergency showers should be located in the immediate work area.
- ☑ Work clothing that has been contaminated with mercuric cyanide should never be worn home where family members can be exposed as well. Contaminated clothing should be laundered at work or by an authorized service by personnel who have been trained in the hazards associated with exposure to mercuric cyanide.
- ☑ The drug n-acetyl penicillamine (NAP) has been used to treat mercury poisoning, with mixed success.
- ☑ Specific engineering controls are recommended for mercury and cyanide by NIOSH. Refer to NIOSH Criteria Document, "Inorganic Mercury" (Publication Number 73-11024) and NIOSH Criteria Document, "Occupational Exposure to Hydrogen Cyanide and Cyanide Salts" (Publication Number 77-108).

RISK ASSESSMENT: ENVIRONMENT

General Assessment

The environment is at risk of exposure during transportation, storage, disposal, or destruction of mercuric cyanide. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance. Accidental spills, large or small, can result in fire, explosion, and possible contamination of the surrounding environmental mediums (water, soil, and air).

Mercuric cyanide is incompatible with many common oxidizers (fluorine), other metals and their salts (magnesium and sodium nitrate) and acids. It is also friction- and impact-sensitive and can easily explode under such conditions. It is also sensitive to heat and light. It reacts with moisture and steam to release explosive hydrogen cyanide gas. In a fire,

mercuric cyanide will emit toxic and poisonous cyanide and mercury fumes. These characteristics require special consideration during any emergency situation involving a leak or spill of mercuric cyanide.

Elemental mercury is a heavy and relatively inert liquid which is oxidized to inorganic mercury (II) under natural conditions. Mercury (II) may combine with an organic fraction to form methyl mercury. Both mercury (II) and methyl mercury can cause environmental contamination. Mercury (II) may enter the environment in industrial or municipal waste treatment discharges, from previously contaminated sediments, and from the weathering of natural rocks. Bacteria may then convert it to methyl mercury. The concentration of mercury (II) in water may be elevated with acid rain due to the scouring of mercury from the air and increased partitioning from the sediment into the water.

☠ *Acute Ecological Effects*

Acute (short-term) toxic effects may include the death of animals, birds, or fish and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to mercuric cyanide. Mercury (II) and methyl mercury have high acute toxicity to aquatic life. Insufficient data are available to evaluate the short-term effects of mercury (II) and methyl mercury exposure to plants, birds or terrestrial animals.

☠* *Chronic Ecological Effects*

Chronic (long-term) toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals. Mercury (II) and methyl mercury have high chronic toxicity to aquatic life. Eating fish contaminated with mercury residues has caused secondary poisoning in humans. Birds or land animals similarly exposed to mercury and its compounds could also be subject to such effects. Insufficient data are available to evaluate the long-term effects of mercuric cyanide exposure to plants.

💧 *Water Solubility*

Mercuric cyanide is soluble in water. Concentrations of 1000 milligrams or more will mix with a liter of water. Mercury itself is insoluble in water.

⌚ *Persistence in the Environment*

Mercury is highly persistent in water, with a half-life greater than 200 days. The half-life of a pollutant is the amount of time it takes for one half of the chemical to be degraded. When released into water, microorganisms convert mercuric salts into methyl mercury which is rapidly taken up by algae and enters the food chain. It concentrates in the edible tissues of fish and, eventually, can cause human poisoning as well.

🌀 *Bioaccumulation in Aquatic Organisms*

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans. The concentration of mercury and methyl mercury found in fish tissues is expected to be considerably higher than the average concentration in the water from which the fish was taken.

🕒 *Recommended Risk-Reduction Measures*

Proper training of all transporters will reduce the likelihood of a mishap or accidents resulting in a leak or spill to the environment. Proper labeling on all containers, trucks, and rail cars will enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

If a spill or leak to the environment has occurred, fire department, emergency response and/or hazardous materials spill personnel should be notified immediately. Do not dry sweep. When vacuuming, a high efficiency particulate air (HEPA) filter should be used, not a standard shop vacuum. Deposit collected materials in sealed drums for disposal. Cleanup should be attempted only by those trained in proper spill containment procedures. Contaminated soils may need to be removed and replaced with clean soil. If mercuric cyanide should contact the water table, aquifer, or navigable waterway, time is of the essence. Mercuric cyanide is soluble in water and total containment and remediation may not be possible. When such spills occur, the local and/or state emergency response authorities should be notified. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of mercuric cyanide. If mercuric cyanide is spilled or leaked, the following specific steps are recommended:

- ☑ Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened for normal work.
- ☑ Ventilate area and remove ignition sources.
- ☑ It may be necessary to dispose of mercuric cyanide as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving mercuric cyanide can present a significant threat to business operations. The loss or damage of equipment or facilities can significantly affect fiscal viability. Lawsuits that may result from personnel injury/death, public exposures, and/or environmental contamination will also require a serious expenditure of resources. Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business. Always remember that anytime the term "reproductive hazard" is used, public emotion, hysteria, and ignorance can run equally high. This must be properly considered whenever developing public relations policies.

🕒 *Recommended Risk-Reduction Measures*

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of such procedures dealing with safety or emergency response. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

Solubility

Soluble in water (especially cold water), nitric acid, acetone, and ammonia.

Appearance and Odor

White or yellow deliquescent, crystalline powder (sugar or sand-like) with no odor.

SECTION IV - FIRE AND EXPLOSION HAZARD DATA

| | |
|---|--|
| Flash Point (method used) Not Determined | Explosive Limits in Air % by Volume LEL: Not Applicable UEL: Not Applicable |
| NFPA Classification Non-Combustible Solid | Autoignition Temperature Not Determined |

Extinguishing Media

Use agent suitable to surrounding fire. Dry chemical or foam may suffice for small fires. For large fires, try fog or regular foam. Exercise caution if water is used (it may increase contamination of area).

Special Fire Fighting Procedures

Poisonous gases are produced in fire. Wear full protective clothing and self-contained breathing apparatus (SCBA). Move containers from fire area if it can be done without risk. Otherwise, use a water spray to keep fire-exposed containers cool until long after fire has been extinguished. Do NOT release runoff from fire-fighting measures to sewers or waterways.

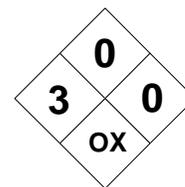

Unusual Fire and Explosion Hazards

Mercuric nitrate is a powerful oxidizer and can greatly accelerate the combustion of ordinary combustible materials.

| SECTION V - REACTIVITY DATA | | | | |

| SECTION VI - HEALTH HAZARD DATA | | | | |
| Primary Route(s) of Entry: | | Inhalation? X | Absorption (skin)? X | Ingestion? X |
| Health Hazards INHALATION: Causes headaches, shortness of breath, cough, chills, fever, congestion, tightness in chest, possible pneumonitis and pulmonary edema. Prolonged contact can cause CNS effects with vertigo, depression, ataxia, emotional instability, and other effects. ABSORPTION: Passes through intact skin to cause effects similar to that of inhalation and ingestion. There can also be visual disturbances, eye burns, and dermatitis. INGESTION: Abdominal pain, diarrhea (possibly bloody), digestive tract irritation, inflammation of the mouth and gums, liver and kidney damage, loose teeth, reduced urine excretion. | | | | |
| Carcinogenicity Unknown Human Unknown Animal | NTP Listed? No | IARC Cancer Review Group? No | OSHA Regulated? 29 CFR 1910.1000 Table Z-1 (as Hg) | Target Organs? Kidney, liver, gastrointestinal tract, CNS. |
| Medical Conditions Generally Aggravated by Exposure Mercury-sensitive people, existing dental and oral problems, kidney disease, respiratory problems, and central nervous system disorders may be aggravated by exposure to mercuric nitrate. | | | | |
| Emergency and First-aid Procedures <u>Eye contact:</u> Flush immediately with water for 15 minutes (minimum); seek medical attention. <u>Skin contact:</u> Remove all contaminated clothing. Immediately wash area with large amounts of soap and water. <u>For inhalation:</u> Remove the person from exposure. Provide respiratory assistance and CPR. Transfer to medical facility. Observe for 48 hours for lung effects. <u>If swallowed:</u> Provide breathing assistance if necessary. Never attempt to give a convulsing or unconscious person anything by mouth. If victim is conscious, give 1-2 glasses of water to dilute and induce vomiting. | | | | |
| SECTION VII - PRECAUTIONS FOR SAFE HANDLING AND USE | | | | |
| Steps to be Taken in Case Material is Released or Spilled Collect powdered material and deposit in sealed drum. Keep those not involved in cleanup from entering area. Do NOT dry sweep (creates airborne dusts). Use a vacuum equipped with a (HEPA) filter. Absorb solution spills in vermiculite or other materials. | | | | |
| Preferred Waste Disposal Method No Citation. | | | | |
| Precautions to be Taken in Handling and Storage Store in tightly closed containers in cool, well-ventilated area. Sources of ignition are prohibited where mercuric nitrate is stored. Keep away from light. Do NOT store on wooden floors. | | | | |
| Other Precautions and Warnings Outside or detached storage facility is recommended. Protect containers from physical damage. | | | | |
| SECTION VIII - CONTROL MEASURES AND PERSONAL PROTECTIVE EQUIPMENT | | | | |
| Respiratory Protection (<i>specify type</i>) Exposure levels are low and difficult to monitor. For best protection, use a supplied-air respirator with a full facepiece or a self-contained breathing apparatus (SCBA) operated in positive pressure mode. | | | | |
| Ventilation Local exhaust or general mechanical systems recommended. | | | | |
| Protective Gloves Impervious Material | | Eye Protection Chemical/Dust Goggles or Face Mask | | Other Protective Clothing Protective Suit or Clothing |
| Work/Hygiene Practices Always wash hands thoroughly after using chemical; never bring food, drink, or smoking materials into vicinity of chemicals. Skin contact must be avoided. | | | | |

MERCURIC NITRATE

CAS: 10045-94-0

**IDENTIFICATION AND TYPICAL USES**

Mercuric nitrate appears as a white or yellow deliquescent crystalline, sugar, sand-like, or powder-like solid with no detectable odor. It is used in the manufacture of felt, as an analytical reagent, in bronzing, in the destruction of phylloxera, and in the manufacture of mercury fulminate.

RISK ASSESSMENT: HEALTH***General Assessment***

Mercuric nitrate is a toxic human poison by three routes of exposure: *inhalation*, *ingestion*, and dermal *absorption*. Mercury accumulates in the body with each exposure. While it is not currently listed as a carcinogenic compound, mutation data have been reported for many mercury compounds. Organic mercury compounds (those that contain carbon) have caused adverse reproductive effects (miscarriages and/or fetal damage) in test animals.

Symptoms of exposure by inhalation of mercury nitrate vapors can include headache, dyspnea, cough, chills, fever, pneumonitis, and delayed pulmonary edema (fluid in the lungs), which can be fatal. Symptoms of pulmonary edema (cough, chest pain, congestion, nausea, dizziness) may be delayed up to 48 hours thereby creating a false sense of security with regard to health exposure risk. Ingestion of mercury or its compounds causes abdominal pain, bloody diarrhea, gastrointestinal irritation, vomiting, cardiac arrhythmia, shock, renal failure, and circulatory collapse.

Repeated exposure from inhalation, absorption, and/or ingestion can cause central nervous system (CNS) effects including vertigo, anxiety, depression, ataxia, emotional instability, kidney injury, brain damage, tremors (the "shakes"), memory loss, metallic taste, discoloration of the skin, sore gums, personality changes, liver damage, loose teeth, decreased urine excretion, visual disturbances, and possible dermatitis.

☠ *Acute Health Effects*

The following acute (short-term) health effects may occur immediately or shortly after exposure to mercuric nitrate:

Skin: Irritation, rash, dermatitis, redness and the appearance of small blisters. Dermal absorption can be quick, causing toxic systemic effects.

Eye: Irritation, inflammation, watering, and swelling, burns, and tissue damage. Ulceration of the conjunctiva and cornea, discoloration of the cornea and lens, tremor of the eyelids, and disturbances in vision.

Lung: Inhalation of mercuric nitrate dusts may cause irritation of the mucous membranes in the respiratory tract causing cough, phlegm, and lung tissue irritation. It can also lead to pneumonitis as well as pulmonary edema, which is a medical emergency and can be fatal.

☠ *Chronic Health Effects*

The following chronic (long-term) health effects may occur at some time after exposure to mercuric nitrate and can last for months or even years:

Cancer Hazards: According to the information presented in the references, mercuric nitrate has not been adequately tested for its ability to cause cancer in test animals. However, mutation (causes genetic changes) data have been documented and many scientists believe that such chemicals may pose a cancer risk in the long-term. More research is required.

Reproductive Hazards: According to information available in the references, organic mercury compounds have been shown to adversely affect reproduction in humans and animals. They can cause the early termination of pregnancies (miscarriages) and may injure the fetus. Mercury may also reduce fertility in both males and females. While inorganic mercury substances (those without carbon), such as mercuric nitrate, have not specifically been shown to be human teratogens, they should still be handled with

caution as they may cause reproductive problems in males and females.

Other Chronic Hazards: High or repeated exposure can cause kidney damage or mercury poisoning with symptoms of sore gums, "shakes" (especially noticeable in handwriting), irritability, increased saliva production, memory loss, extreme shyness, weakness, loss of teeth, poor appetite, and metallic taste. Serious personality changes and brain damage can occur, especially if exposure continues. Repeated skin contact may cause gray discoloration and a skin allergy may develop. If this happens, even small future exposures can cause rash. Repeated exposures may also cause reduced peripheral vision and brown staining of the eye. Mercury can accumulate in the body on prolonged exposure and it may take years for the body to dispose of mercury.

🕒 **Recommended Risk-Reduction Measures**

Personnel should avoid direct contact with mercuric nitrate. Mercury is an extremely toxic, cumulative poison. If a less toxic chemical cannot be substituted for a hazardous material, then *engineering controls* are the most effective method of reducing exposures.

The best protection is to enclose operations and/or provide local exhaust ventilation at the site of chemical release. While not always operationally feasible, isolating operations can also reduce exposure. Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around mercuric nitrate. Exposure levels for mercury are extremely low (0.1 mg/m^3) and difficult to monitor accurately. A full facepiece respirator with a high-efficiency particulate air (HEPA) filter equipped with a dust/mist/fume pre-filter may suffice. However, for the best protection use a supplied-air respirator with a full facepiece operated in positive pressure mode or an MSHA/NIOSH-approved self-contained breathing apparatus (SCBA) with full facepiece operated in pressure demand or other continuous flow mode. If a full facepiece is not available, then chemical/dust goggles should be worn to protect the eyes. Whenever a chemical dust hazard exists, a face shield and a protective apron should be worn. To prevent hand and skin exposures, impervious rubber gloves should be used. Glove manufacturers should be contacted and permeation studies obtained *before* final glove selections are made. Skin contact must be prevented. Protective suits and clothing should be used.

Administrative controls should also be in place to minimize the potential for human exposures. These

may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with mercuric nitrate dusts or solutions. All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where mercuric nitrate is used or stored. Before first exposure and every six to twelve months thereafter, a complete medical history and examination is recommended, including the following:

- Examination of the nervous system (taking note of any problems with person's handwriting).
- Routine urinalysis and special urine test for mercury (should be less than 0.02 mg/liter).
- Eye examination.
- Lung function tests for frequent exposures.

If symptoms develop or overexposure is suspected, the following additional tests are recommended:

- Consider nerve conduction tests.
- Urinary enzyme and neurological behavior tests.
- Serum mercury tests.
- Consider chest X-ray following acute overexposure (may be negative if taken immediately after exposure due to delayed onset of pulmonary edema).

Any evaluation should include a careful history of past and present symptoms with a medical examination. Medical tests that look for damage already done are not a substitute for controlling exposure. Also, since smoking can cause heart disease, emphysema, and a number of other respiratory disorders, smokers exposed to lung irritants such as mercuric nitrate dusts and fumes may experience symptoms much more quickly than non-smokers under the same conditions of exposure. Other mixed exposures occur when personnel use creams to whiten or bleach the skin that contain mercury. If so, their use increases exposure risk. Persons who are allergic to mercury may react to Mercurochrome or Merthiolate, which also contain mercury. Prudent risk management requires proper consideration of *all* exposure factors.

Other methods to reduce exposure include:

- Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not

used, respiratory protection should be provided and its use mandatory.

- ☑ Always ensure that proper protective clothing is worn when using chemical substances.
- ☑ Wash thoroughly immediately after exposure to mercuric nitrate and at the end of the work shift or before eating, drinking, or smoking.
- ☑ Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of mercuric nitrate should be communicated to all exposed and potentially exposed workers.
- ☑ Eye wash stations and emergency showers should be located in the immediate work area.
- ☑ Work clothing that has been contaminated with mercuric nitrate should never be worn home where family members can be exposed as well. Contaminated clothing should be laundered at work or by an authorized service by personnel who have been trained in the hazards associated with exposure to mercuric nitrate.
- ☑ The drug n-acetyl penicillamine (NAP) has been used in the past to treat mercury poisoning, with mixed success.
- ☑ Specific engineering controls are recommended for mercury by NIOSH. Refer to NIOSH Criteria Document, "Inorganic Mercury" (Publication Number 73-11024).

RISK ASSESSMENT: ENVIRONMENT

General Assessment

The environment is at risk of exposure during transportation, storage, disposal, or destruction of mercuric nitrate. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance. Accidental spills, large or small, can result in fire, explosion, and possible contamination of the surrounding environmental mediums (water, soil, and air).

Mercuric nitrate is incompatible with many common materials. It can react with acetylene, ethanol, phosphine, potassium cyanide, ferrocene, and sulfur. Reactions can be vigorous and violent. It is also sensitive to heat and light. In a fire, mercuric nitrate will emit toxic and poisonous fumes of mercury and nitrogen. These characteristics require special considera-

tion during any emergency situation involving a leak or spill of mercuric nitrate.

Elemental mercury is a heavy and relatively inert liquid which is oxidized to inorganic mercury (II) under natural conditions. Mercury (II) may combine with an organic fraction to form methyl mercury. Both mercury (II) and methyl mercury can cause environmental contamination. Mercury (II) may enter the environment in industrial or municipal waste treatment discharges, from previously contaminated sediments, and from the weathering of natural rocks. Bacteria may then convert it to methyl mercury. The concentration of mercury (II) in water may be elevated with acid rain due to the scouring of mercury from the air and increased partitioning from the sediment into the water.

☠ *Acute Ecological Effects*

Acute (short-term) toxic effects may include the death of animals, birds, or fish and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to mercuric nitrate. Mercury (II) and methyl mercury have high acute toxicity to aquatic life. Insufficient data are available to evaluate the short-term effects of mercury (II) and methyl mercury exposure to plants, birds or terrestrial animals.

🕒 *Chronic Ecological Effects*

Chronic (long-term) toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals. Mercury (II) and methyl mercury have high chronic toxicity to aquatic life. Eating fish contaminated with mercury residues has caused secondary poisoning in humans. Birds or land animals similarly exposed to mercury and its compounds could also be subject to such effects. Insufficient data are available to evaluate the long-term effects of mercuric nitrate exposure to plants.

💧 *Water Solubility*

Mercuric nitrate is soluble in water. Concentrations of 1000 milligrams or more will mix with a liter of water.

🕒 *Persistence in the Environment*

Mercury is highly persistent in water, with a half-life greater than 200 days. The half-life of a pollutant is the amount of time it takes for one half of the chemical to be degraded. When released into water, micro-

organisms convert mercuric salts into methyl mercury which is rapidly taken up by algae and enters the food chain. It concentrates in the edible tissues of fish and, eventually, can cause human poisoning as well.

🌀 *Bioaccumulation in Aquatic Organisms*

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans. The concentration of mercury and methyl mercury found in fish tissues is expected to be considerably higher than the average concentration in the water from which the fish was taken.

🕒 *Recommended Risk-Reduction Measures*

Proper training of all transporters will reduce the likelihood of a mishap or accidents resulting in a leak or spill to the environment. Proper labeling on all containers, trucks, and rail cars will enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

If a spill or leak to the environment has occurred, fire department, emergency response and/or hazardous materials spill personnel should be notified immediately. Do not dry sweep. When vacuuming, a high-efficiency particulate air (HEPA) filter should be used, not a standard shop vacuum. Deposit collected materials in sealed drums for disposal. Cleanup should be attempted only by those trained in proper spill containment procedures. Contaminated soils may need to be removed and replaced with clean soil. If mercuric nitrate should contact the water table, aquifer, or navigable waterway, time is of the essence. Mercuric nitrate is soluble in water and total containment and remediation may not be possible. When such spills occur, the local and/or state emergency response authorities should be notified. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of mercuric nitrate. If mercuric nitrate is spilled or leaked, the following specific steps are recommended:

- ☑ Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened for normal work.
- ☑ Ventilate area and remove all ignition sources.

- ☑ It may be necessary to dispose of mercuric nitrate as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving mercuric nitrate can present a significant threat to business operations. The loss or damage of equipment or facilities can significantly affect fiscal viability. Lawsuits that may result from personnel injury/death, public exposures, and/or environmental contamination will also require a serious expenditure of resources. Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business. Always remember that anytime the term "reproductive hazard" is used, public emotion, hysteria, and ignorance can run equally high. This must be properly considered whenever developing public relations policies.

🕒 *Recommended Risk-Reduction Measures*

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of such procedures dealing with safety or emergency response. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

| Vapor Density (Air = 1) 7.5 | Melting Point 932°F (500°C) Decomposes |

Solubility

Insoluble in water. Soluble in dilute hydrochloric and nitric acids. Insoluble in alcohol, acetone, ammonia, and ether.

Appearance and Odor

Black to grayish-black powder. No odor.

SECTION IV - FIRE AND EXPLOSION HAZARD DATA

| | |
|---|---|
| Flash Point (method used) Not Determined | Explosive Limits in Air % by Volume LEL: Not Applicable UEL: Not Applicable |
| NFPA Classification Non-Combustible Solid | Autoignition Temperature Not Determined |

Extinguishing Media

Use agent suitable to surrounding fire. Dry chemical, carbon dioxide, alcohol foam, or water.

Special Fire Fighting Procedures

Poisonous gases are produced in fire. Wear full protective clothing and self-contained breathing apparatus (SCBA). Move containers from fire area if it can be done without risk. Otherwise, use a water spray to keep fire-exposed containers cool until long after fire has been extinguished. Do NOT release runoff from fire-fighting measures to sewers or waterways.

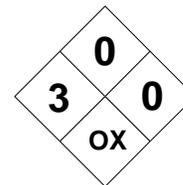

Unusual Fire and Explosion Hazards

Mercuric oxide is a powerful oxidizer and can greatly accelerate the combustion of ordinary combustible materials. Evacuate nonessential personnel a 1500-foot radius away from fire danger area.

| SECTION V - REACTIVITY DATA | | | | |
|--|----------------------------|--|--|--|
| Stability | | Conditions to Avoid Mercuric oxide is stable under normal conditions of temperature and pressure. However, it will gradually decompose to metallic mercury when heated or exposed to light. Keep away from incompatible materials. | | |

| Health Hazards INHALATION: Causes headaches, shortness of breath, cough, chills, fever, congestion, tightness in chest, possible pneumonitis and pulmonary edema. Prolonged contact can cause CNS effects with vertigo, depression, ataxia, emotional instability, and other effects. ABSORPTION: Passes through intact skin to cause effects similar to that of inhalation and ingestion. There can also be visual disturbances, eye burns, and dermatitis. INGESTION: Abdominal pain, diarrhea (possibly bloody), digestive tract irritation, inflammation of the mouth and gums, vomiting with blood, shallow breathing, paleness, collapse, death. | | | | |
| Carcinogenicity Unknown Human Unknown Animal | NTP Listed? No | IARC Cancer Review Group? No | OSHA Regulated? 29 CFR 1910.1000 Table Z-1 (as Hg) | Target Organs? Kidney, liver, gastrointestinal tract, CNS, skin. |
| Medical Conditions Generally Aggravated by Exposure Mercury-sensitive people, existing dental and oral problems, kidney disease, respiratory problems, and central nervous system disorders may be aggravated by exposure to mercuric oxide. | | | | |
| Emergency and First-aid Procedures <u>Eye contact:</u> Flush immediately with water for 15 minutes (minimum); seek medical attention. <u>Skin contact:</u> Remove all contaminated clothing. Immediately wash area with large amounts of soap and water. For <u>inhalation:</u> Remove the person from exposure. Provide respiratory assistance and CPR. Transfer to medical facility. Observe for 48 hours for lung effects. If <u>swallowed:</u> Provide breathing assistance if necessary. Never attempt to give a convulsing or unconscious person anything by mouth. If victim is conscious, give 1-2 glasses of water to dilute and induce vomiting. | | | | |
| SECTION VII - PRECAUTIONS FOR SAFE HANDLING AND USE | | | | |
| Steps to be Taken in Case Material is Released or Spilled Collect powdered material and deposit in sealed drum. Keep those not involved in cleanup from entering area. Do NOT dry sweep (creates airborne dusts). Use a vacuum equipped with a (HEPA) filter. Damp mop residue. Absorb solution spills in vermiculite or other materials. | | | | |
| Preferred Waste Disposal Method Add chlorine to oxidize; absorb with activated carbon/sulfur. Return spent resin to the supplier. | | | | |
| Precautions to be Taken in Handling and Storage Store in tightly closed containers in cool, well-ventilated area. Sources of ignition are prohibited where mercuric oxide is stored. Keep away from light. Do NOT store on wooden floors. | | | | |
| Other Precautions and Warnings Outside or detached storage facility is recommended. Protect containers from physical damage. | | | | |
| SECTION VIII - CONTROL MEASURES AND PERSONAL PROTECTIVE EQUIPMENT | | | | |
| Respiratory Protection (<i>specify type</i>) Exposure levels are low and difficult to monitor. For best protection, use a supplied-air respirator with a full facepiece or a self-contained breathing apparatus (SCBA) operated in positive pressure mode. | | | | |
| Ventilation Local exhaust or general mechanical systems recommended. | | | | |
| Protective Gloves Impervious Material | | Eye Protection Chemical/Dust Goggles or Face Mask | | Other Protective Clothing Protective Suit or Clothing |
| Work/Hygiene Practices Always wash hands thoroughly after using chemical; never bring food, drink, or smoking materials into vicinity of chemicals. Skin contact must be avoided. | | | | |

MERCURIC OXIDEHg₂O

CAS: 15829-53-5

**IDENTIFICATION AND TYPICAL USES**

Mercuric oxide appears as a black crystalline, sugar or sand-like powder with no detectable odor. It is used in paint and ceramic pigment, as an analytical reagent, in batteries, as a fixative in selenium determination, as a chemical intermediate, a preservative in cosmetics, and an antiseptic in pharmaceuticals.

RISK ASSESSMENT: HEALTH**General Assessment**

Mercuric oxide is a toxic human poison by three routes of exposure: *inhalation*, *ingestion*, and dermal *absorption*. Mercury accumulates in the body with each exposure. While it is not currently listed as a carcinogenic compound, mutation data have been reported for many mercury compounds. Organic mercury compounds (those that contain carbon) have caused adverse reproductive effects (miscarriages and/or fetal damage) in test animals.

Inhalation of mercury oxide vapors can cause immediate irritation to the eyes, nose, and mucosa of the respiratory tract. It may cause neurologic disturbances, weight loss, and possible low sperm count. Other symptoms may include headache, dyspnea, cough, chills, and fever. Ingestion of mercury or its compounds causes toxicity that generally begins with burning mouth pain, feeling of tightness or constriction, and an ashen-gray coloration of the mucosa. Symptoms progress to abdominal pain with bloody vomiting (due to digestive hemorrhage), intense thirst, bloody diarrhea, metallic taste the mouth, excessive salivation, rapid and weak pulse, difficulty breathing, pale complexion, collapse, and death.

Repeated exposure from inhalation, absorption, and/or ingestion can cause central nervous system (CNS) effects including vertigo, anxiety, depression, ataxia, emotional instability, kidney injury, brain damage, tremors (the "shakes"), memory loss, discoloration of the skin, sore gums and ulcerative gingivitis, personality changes, liver damage, loose teeth, de-

creased urine excretion, visual disturbances, and possible dermatitis.

☠ Acute Health Effects

The following acute (short-term) health effects may occur immediately or shortly after exposure to mercuric oxide:

Skin: Irritation, rash, dermatitis, redness and the appearance of small blisters. Dermal absorption can be quick, causing toxic systemic effects.

Eye: Irritation, inflammation, watering, and swelling, burns, and tissue damage. Ulceration of the conjunctiva and cornea, discoloration of the cornea and lens, tremor of the eyelids, and disturbances in vision.

Lung: Inhalation of mercuric oxide dusts may cause irritation of the mucous membranes in the respiratory tract causing cough, phlegm, and lung tissue irritation.

☘ Chronic Health Effects

The following chronic (long-term) health effects may occur at some time after exposure to mercuric oxide and can last for months or even years:

Cancer Hazards: According to the information presented in the references, mercuric oxide has not been adequately tested for its ability to cause cancer in test animals. However, mutation (causes genetic changes) data have been documented for many mercury compounds and many scientists believe that such chemicals may pose a cancer risk in the long-term. More research is required.

Reproductive Hazards: According to information available in the references, organic mercury compounds have been shown to adversely affect reproduction in humans and animals. They can cause the early termination of pregnancies (miscarriages) and may injure the fetus. Mercury may also reduce fertil-

ity in both males and females. While inorganic mercury substances (those without carbon), such as mercuric oxide, have not specifically been shown to be human teratogens, they should still be handled with caution as they may cause reproductive problems in males and females.

Other Chronic Hazards: High or repeated exposure can cause kidney damage or mercury poisoning with symptoms of sore gums, "shakes" (especially noticeable in handwriting), irritability, increased saliva production, memory loss, extreme shyness, weakness, loss of teeth, poor appetite, and metallic taste. Serious personality changes and brain damage can occur, especially if exposure continues. Repeated skin contact may cause gray discoloration and a skin allergy may develop. If this happens, even small future exposures can cause rash. Repeated exposures may also cause reduced peripheral vision and brown staining of the eye. Mercury can accumulate in the body on prolonged exposure and it may take years for the body to dispose of mercury.

🔊 **Recommended Risk-Reduction Measures**

Personnel should avoid direct contact with mercuric oxide. Mercury is an extremely toxic, cumulative poison. If a less toxic chemical cannot be substituted for a hazardous material, then *engineering controls* are the most effective method of reducing exposures.

The best protection is to enclose operations and/or provide local exhaust ventilation at the site of chemical release. While not always operationally feasible, isolating operations can also reduce exposure. Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around mercuric oxide. Exposure levels for mercury are extremely low (0.1 mg/m^3) and difficult to monitor accurately. A full facepiece respirator with a high-efficiency particulate air (HEPA) filter equipped with a dust/mist/fume pre-filter may suffice. However, for the best protection use a supplied-air respirator with a full facepiece operated in positive pressure mode or an MSHA/NIOSH-approved self-contained breathing apparatus (SCBA) with full facepiece operated in pressure demand or other continuous flow mode. If a full facepiece is not available, then chemical/dust goggles should be worn to protect the eyes. Whenever a chemical dust hazard exists, a face shield and a protective apron should be worn. To prevent hand and skin exposures, impervious rubber gloves should be used. Glove manufacturers should be contacted and permeation studies obtained *before*

final glove selections are made. Skin contact must be prevented. Protective suits and clothing should be used.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with mercuric oxide dusts or solutions. All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where mercuric oxide is used or stored. Before first exposure and every six to twelve months thereafter, a complete medical history and examination is recommended, including the following:

- ☑ Examination of the nervous system (taking note of any problems with person's handwriting).
- ☑ Routine urinalysis and special urine test for mercury (should be less than 0.02 mg/liter).
- ☑ Eye examination.
- ☑ Lung function tests for frequent exposures.

If symptoms develop or overexposure is suspected, the following additional tests are recommended:

- ☑ Consider nerve conduction tests.
- ☑ Urinary enzyme and neurological behavior tests.
- ☑ Serum mercury tests.

Any evaluation should include a careful history of past and present symptoms with a medical examination. Medical tests that look for damage already done are not a substitute for controlling exposure. Also, mixed exposures occur when personnel use creams to whiten or bleach the skin that contain mercury. If so, their use increases exposure risk. Persons who are allergic to mercury may react to Mercurochrome or Merthiolate, which also contain mercury. Prudent risk management requires proper consideration of *all* exposure factors.

Other methods to reduce exposure include:

- ☑ Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not used, respiratory protection should be provided and its use mandatory.
- ☑ Always ensure that proper protective clothing is worn when using chemical substances and that personnel are trained in its use and care.

- ☑ Wash thoroughly immediately after exposure to mercuric oxide and at the end of the work shift or before eating, drinking, or smoking.
- ☑ Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of mercuric oxide should be communicated to all exposed and potentially exposed workers.
- ☑ Eye wash stations and emergency showers should be located in the immediate work area.
- ☑ Work clothing that has been contaminated with mercuric oxide should never be worn home where family members can be exposed as well. Contaminated clothing should be laundered at work or by an authorized service by personnel who have been trained in the hazards associated with exposure to mercuric oxide.
- ☑ The drug n-acetyl penicillamine (NAP) has been used in the past to treat mercury poisoning, with mixed success.
- ☑ Specific engineering controls are recommended for mercury by NIOSH. Refer to NIOSH Criteria Document, "Inorganic Mercury" (Publication Number 73-11024).

RISK ASSESSMENT: ENVIRONMENT

General Assessment

The environment is at risk of exposure during transportation, storage, disposal, or destruction of mercuric oxide. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance. Accidental spills, large or small, can result in fire, explosion, and possible contamination of the surrounding environmental mediums (water, soil, and air).

Mercuric oxide is incompatible with many common materials. It can react explosively with hydrogen peroxide, chlorine plus ethylene, molten potassium, molten sodium, and sulfur. Reactions with non-metals and alkaline metals can also be vigorous and violent. It is also sensitive to heat and light and will decompose to mercury and oxygen when exposed to either. In a fire, mercuric oxide will emit toxic and poisonous fumes of mercury. These characteristics require special consideration during any emergency situation involving a leak or spill of mercuric oxide.

Elemental mercury is a heavy and relatively inert liquid which is oxidized to inorganic mercury (II) under natural conditions. Mercury (II) may combine with an organic fraction to form methyl mercury. Both mercury (II) and methyl mercury can cause environmental contamination. Mercury (II) may enter the environment in industrial or municipal waste treatment discharges, from previously contaminated sediments, and from the weathering of natural rocks. Bacteria may then convert it to methyl mercury. The concentration of mercury (II) in water may be elevated with acid rain due to the scouring of mercury from the air and increased partitioning from the sediment into the water.

☠ *Acute Ecological Effects*

Acute (short-term) toxic effects may include the death of animals, birds, or fish and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to mercuric oxide.

Mercury (II) and methyl mercury have high acute toxicity to aquatic life. Insufficient data are available to evaluate the short-term effects of mercury (II) and methyl mercury exposure to plants, birds or terrestrial animals.

⚗ *Chronic Ecological Effects*

Chronic (long-term) toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals.

Mercury (II) and methyl mercury have high chronic toxicity to aquatic life. Eating fish contaminated with mercury residues has caused secondary poisoning in humans. Birds or land animals similarly exposed to mercury and its compounds could also be subject to such effects. Insufficient data are available to evaluate the long-term effects of mercuric oxide exposure to plants.

💧 *Water Solubility*

Mercuric oxide is insoluble in water. Concentrations of less than 1 milligram will not mix with a liter of water.

🕒 *Persistence in the Environment*

Mercury is highly persistent in water, with a half-life greater than 200 days. The half-life of a pollutant is the amount of time it takes for one half of the chemi-

cal to be degraded. When released into water, microorganisms convert mercuric salts into methyl mercury which is rapidly taken up by algae and enters the food chain. It concentrates in the edible tissues of fish and, eventually, can cause human poisoning as well.

🌀 Bioaccumulation in Aquatic Organisms

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans.

The concentration of mercury and methyl mercury found in fish tissues is expected to be considerably higher than the average concentration in the water from which the fish was taken.

🕒 Recommended Risk-Reduction Measures

Proper training of all transporters will reduce the likelihood of a mishap or accidents resulting in a leak or spill to the environment. Proper labeling on all containers, trucks, and rail cars will enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

If a spill or leak to the environment has occurred, fire department, emergency response and/or hazardous materials spill personnel should be notified immediately. Do not dry sweep. When vacuuming, a high-efficiency particulate air (HEPA) filter should be used, not a standard shop vacuum. Alternatively, commercially available mercury spill cleanup kits can be used. Deposit collected materials in sealed drums for disposal. Cleanup should be attempted only by those trained in proper spill containment procedures. Contaminated soils may need to be removed and replaced with clean soil. If mercuric oxide should contact the water table, aquifer, or navigable waterway, time is of the essence. Mercuric oxide is insoluble in water and total containment and remediation may be possible. When such spills occur, the local and/or state emergency response authorities should be notified. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of mercuric oxide.

If mercuric oxide is spilled or leaked, the following specific steps are recommended:

- ☑ Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened for normal work.
- ☑ Ventilate area and remove all ignition sources.
- ☑ It may be necessary to dispose of mercuric oxide as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving mercuric oxide can present a significant threat to business operations. The loss or damage of equipment or facilities can significantly affect fiscal viability. Lawsuits that may result from personnel injury/death, public exposures, and/or environmental contamination will also require a serious expenditure of resources. Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business. Always remember that anytime the term "reproductive hazard" is used, public emotion, hysteria, and ignorance can run equally high. This must be properly considered whenever developing public relations policies.

🕒 Recommended Risk-Reduction Measures

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of such procedures dealing with safety or emergency response. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

MERCURIC SULFATE

HgSO₄

CAS: 7783-35-9

IDENTIFICATION AND TYPICAL USES

Mercuric sulfate appears as a white crystalline, sugar or sand-like solid with no detectable odor. It is used as a calomel and corrosive sublimate, as a catalyst in the conversion of acetylene to acetaldehyde, for extracting gold and silver from roasted pyrites, and as a battery electrolyte.

RISK ASSESSMENT: HEALTH

General Assessment

Mercuric sulfate is a toxic human poison by three routes of exposure: *inhalation*, *ingestion*, and *dermal absorption*. Mercury accumulates in the body with each exposure. While it is not currently listed as a carcinogenic compound, mutation data have been reported for many mercury compounds. Organic mercury compounds (those that contain carbon) have caused adverse reproductive effects (miscarriages and/or fetal damage) in test animals.

Symptoms of exposure by inhalation of mercury sulfate vapors can include immediate irritation of the mouth and throat, headache, dyspnea, cough, chills, fever, and bronchial irritation.

Ingestion of mercury or its compounds causes abdominal pain, bloody diarrhea, gastrointestinal irritation, vomiting, and cardiac arrhythmia. There will be almost immediate necrosis in the mouth, throat, esophagus, and stomach. Up to 72 hours after ingestion, there can still be inflammation of the mouth tissues and kidney inflammation or disease. Death can occur from total renal failure.

Repeated exposure from inhalation, absorption, and/or ingestion can cause central nervous system (CNS) effects including vertigo, anxiety, depression, ataxia, emotional instability, kidney injury, brain damage, tremors (the "shakes"), memory loss, metallic taste, discoloration of the skin, sore gums, personality

changes, liver damage, loose teeth, necrosis of the jaw, decreased urine excretion, visual disturbances, and possible development of dermatitis.

☠ *Acute Health Effects*

The following acute (short-term) health effects may occur immediately or shortly after exposure to mercuric sulfate:

Skin: Corrosion to the surface, irritation, rash, dermatitis, and possible redness and the appearance of small blisters. Dermal absorption can be quick and will cause toxic systemic effects.

Eye: Irritation, inflammation, swelling, conjunctiva and corneal ulceration, burns, and tissue damage.

Lung: Inhalation of mercuric sulfate dusts may cause irritation of the mucous membranes in the respiratory tract causing cough, phlegm, and lung tissue irritation.

☘ *Chronic Health Effects*

The following chronic (long-term) health effects may occur at some time after exposure to mercuric sulfate and can last for months or even years:

Cancer Hazards: According to the information presented in the references, mercuric sulfate has not been adequately tested for its ability to cause cancer in test animals. However, mutation (causes genetic changes) data have been documented and many scientists believe that such chemicals may pose a cancer risk in the long-term. More research is required.

Reproductive Hazards: According to information available in the references, mercuric sulfate has not been specifically tested for its ability to cause cancer in test animals. However, some organic mercury compounds have been shown to adversely affect re-

production in humans and animals. They can cause the early termination of pregnancies (miscarriages) and may injure the fetus. Mercury may also reduce fertility in both males and females. While inorganic mercury substances (those without carbon), have not specifically been shown to be human teratogens, they should still be handled with caution as they may cause reproductive problems in males and females.

Other Chronic Hazards: High or repeated exposure can cause kidney damage or mercury poisoning with symptoms of sore gums, "shakes" (especially noticeable in handwriting), irritability, increased saliva production, memory loss, extreme shyness, weakness, loss of teeth, poor appetite, and metallic taste. Serious personality changes and brain damage can occur, especially if exposure continues. Repeated skin contact may cause gray discoloration and a skin allergy may develop. If this happens, even small future exposures can cause rash. Repeated exposures may also cause reduced peripheral vision and brown staining of the eye. Mercury can accumulate in the body on prolonged exposure and it may take months or years for the body to dispose of excess mercury.

🔹 **Recommended Risk-Reduction Measures**

Personnel should avoid direct contact with mercuric sulfate. Mercury is an extremely toxic, cumulative poison. If a less toxic chemical cannot be substituted for a hazardous material, then *engineering controls* are the most effective method of reducing exposures.

The best protection is to enclose operations and/or provide local exhaust ventilation at the site of chemical release. While not always operationally feasible, isolating operations can also reduce exposure. Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around mercuric sulfate. Exposure levels for mercury are extremely low (0.1 mg/m^3) and difficult to monitor accurately. A full facepiece respirator with a high-efficiency particulate air (HEPA) filter equipped with a dust/mist/fume pre-filter may suffice. However, for the best protection use a supplied-air respirator with a full facepiece operated in positive pressure mode or an MSHA/NIOSH-approved self-contained breathing apparatus (SCBA) with full facepiece operated in pressure demand or other continuous flow mode. If a full facepiece is not available, then chemical/dust goggles should be worn to protect the eyes. Whenever a chemical dust hazard exists, a face shield and a protective apron should be worn. To prevent hand and skin exposures, impervious rubber

gloves should be used. Glove manufacturers should be contacted and permeation studies obtained *before* final glove selections are made. Mercury salts such as mercuric sulfate are among mercury's most irritating and acutely toxic compounds. They are corrosive to skin tissues. Skin contact must be prevented.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with mercuric sulfate dusts or solutions. All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where mercuric sulfate is used or stored. Before first exposure and every six to twelve months thereafter, a complete medical history and examination is recommended, including the following:

- Examination of the nervous system (taking note of any problems with person's handwriting).
- Routine urinalysis and special urine test for mercury (should be less than 0.02 mg/liter).
- Eye examination.
- Lung function tests for frequent exposures.

If symptoms develop or overexposure is suspected, the above listed tests should be repeated, along with the following recommended tests:

- Consider nerve conduction tests.
- Urinary enzyme and neurological behavior tests.
- Serum mercury tests.

Any evaluation should include a careful history of past and present symptoms with a medical examination. Medical tests that look for damage already done are not a substitute for controlling exposure. Also, mixed exposures occur when personnel use creams to whiten or bleach the skin that contain mercury. If so, their use increases exposure risk. Persons who are allergic to mercury may react to Mercurochrome or Merthiolate, which also contain mercury. Prudent risk management requires proper consideration of *all* exposure factors.

Other methods to reduce exposure include:

- Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not

used, respiratory protection should be provided and its use mandatory.

- ☑ Always ensure that proper protective clothing is worn when using chemical substances and that personnel are trained in its use and care.
- ☑ Wash thoroughly immediately after exposure to mercuric sulfate and at the end of the work shift or before eating, drinking, or smoking.
- ☑ Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of mercuric sulfate should be communicated to all exposed and potentially exposed workers.
- ☑ Eye wash stations and emergency showers should be located in the immediate work area.
- ☑ Work clothing that has been contaminated with mercuric sulfate should never be worn home where family members can be exposed as well. Contaminated clothing should be laundered at work or by an authorized service by personnel who have been trained in the hazards associated with exposure to mercuric sulfate.
- ☑ The drug n-acetyl penicillamine (NAP) has been used to treat mercury poisoning, with mixed success.
- ☑ Specific engineering controls are recommended for mercury by NIOSH. Refer to NIOSH Criteria Document, "Inorganic Mercury" (Publication Number 73-11024).

RISK ASSESSMENT: ENVIRONMENT

General Assessment

The environment is at risk of exposure during transportation, storage, disposal, or destruction of mercuric sulfate. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance. Accidental spills, large or small, can result in fire, explosion, and possible contamination of the surrounding environmental mediums (water, soil, and air).

Mercuric sulfate is incompatible with many common materials. Reactions can be vigorous and violent. It decomposes in water into a yellow, insoluble, basic sulfate and free sulfuric acid. It will violently absorb gaseous hydrogen chlorides at high temperatures. It is corrosive to many metals, including aluminum, zinc,

copper, and lead. In a fire, mercuric sulfate will emit toxic and poisonous fumes of mercury and sulfur oxide. These characteristics require special consideration during any emergency situation involving a leak or spill of mercuric sulfate.

Elemental mercury is a heavy and relatively inert liquid which is oxidized to inorganic mercury (II) under natural conditions. Mercury (II) may combine with an organic fraction to form methyl mercury. Both mercury (II) and methyl mercury can cause environmental contamination. Mercury (II) may enter the environment in industrial or municipal waste treatment discharges, from previously contaminated sediments, and from the weathering of natural rocks. Bacteria may then convert it to methyl mercury. The concentration of mercury (II) in water may be elevated with acid rain due to the scouring of mercury from the air and increased partitioning from the sediment into the water.

☠ Acute Ecological Effects

Acute (short-term) toxic effects may include the death of animals, birds, or fish and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to mercuric sulfate.

Mercury (II) and methyl mercury have high acute toxicity to aquatic life. Insufficient data are available to evaluate the short-term effects of mercury (II) and methyl mercury exposure to plants, birds or terrestrial animals.

☪ Chronic Ecological Effects

Chronic (long-term) toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals.

Mercury (II) and methyl mercury have high chronic toxicity to aquatic life. Eating fish contaminated with mercury residues has caused secondary poisoning in humans. Birds or land animals exposed to mercury and its compounds could also be subject to such effects. Insufficient data are available to evaluate the long-term effects of mercuric sulfate exposure to plants.

◆ Water Solubility

Mercuric sulfate is soluble in water. Concentrations of 1000 milligrams or more will mix with a liter of

water. Mercury is insoluble in the aquatic environment.

Persistence in the Environment

Mercury is highly persistent in water, with a half-life greater than 200 days. The half-life of a pollutant is the amount of time it takes for one half of the chemical to be degraded. When released into water, microorganisms convert mercuric salts into methyl mercury which is rapidly taken up by algae and enters the food chain. It concentrates in the edible tissues of fish and, eventually, can cause human poisoning as well.

Bioaccumulation in Aquatic Organisms

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans. The concentration of mercury and methyl mercury found in fish tissues is expected to be considerably higher than the average concentration in the water from which the fish was taken.

Recommended Risk-Reduction Measures

Proper training of all transporters will reduce the likelihood of a mishap or accidents resulting in a leak or spill to the environment. Proper labeling on all containers, trucks, and rail cars will enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

If a spill or leak to the environment has occurred, fire department, emergency response and/or hazardous materials spill personnel should be notified immediately. Do not dry sweep. When vacuuming, a high efficiency particulate air (HEPA) filter should be used, not a standard shop vacuum. Otherwise, commercially available mercury spill cleanup kits should be considered. Deposit collected materials in sealed drums for disposal. Cleanup should be attempted only by those trained in proper spill containment procedures. Contaminated soils may need to be removed and replaced with clean soil. If mercuric sulfate should contact the water table, aquifer, or navigable waterway, response activities should be prompt. When such spills occur, the local and/or state emergency response authorities should be notified. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, stor-

age, or disposal of mercuric sulfate. If mercuric sulfate is spilled or leaked, the following additional steps are recommended:

- Ventilate area and remove all ignition sources.
- It may be necessary to dispose of mercuric sulfate as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving mercuric sulfate can present a significant threat to business operations. The loss or damage of equipment or facilities can significantly affect fiscal viability. Lawsuits that may result from personnel injury/death, public exposures, and/or environmental contamination will also require a serious expenditure of resources. Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business. Always remember that anytime the term "reproductive hazard" is used, public emotion, hysteria, and ignorance can run equally high. This must be properly considered whenever developing public relations policies.

Recommended Risk-Reduction Measures

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of such procedures dealing with safety or emergency response. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

| Primary Route(s) of Entry: | | Inhalation? X | Absorption (skin)? X |
| Ingestion? | | | |
| Health Hazards INHALATION: Causes immediate and severe respiratory damage. Also affects the central nervous with symptoms of sleeplessness, muscle weakness, anorexia, headache, tinnitus, headache, diarrhea, liver changes, fever, gum and mouth inflammation, chest pain, dyspnea, cough and phlegm, salivation, bronchitis, pulmonary edema, and pneumonitis. ABSORPTION: Passes through intact skin to cause effects similar to that of inhalation and ingestion. There can also be visual disturbances, eye burns, and dermatitis. Skin irritation can be severe if mercury remains in contact for long periods. INGESTION: Generally innocuous on ingestion (unless large amounts are ingested). | | | |
| Carcinogenicity Unknown Human Unknown Animal | NTP Listed? No | IARC Cancer Review Group? No | OSHA Regulated? 29 CFR 1910.1000 Table Z-1 (as Hg) |
| Target Organs? Skin, eyes, kidney, liver, GI tract, CNS, resp. sys. | | | |
| Medical Conditions Generally Aggravated by Exposure Central nervous system disorders, and existing mercury allergies may be aggravated by exposure. | | | |
| Emergency and First-aid Procedures Eye contact: Flush immediately with water for 15 minutes (minimum); seek medical attention. Skin contact: Remove all contaminated clothing. Immediately wash area with large amounts of soap and water. For reddened or blistered skin, seek medical assistance. For inhalation: Remove the person from exposure. Provide respiratory assistance and CPR. Transfer to medical facility. Observe for 48 hours for lung effects. If swallowed: Contact poison control center for advice. Mercury will generally pass through the digestive system without incident. However, large doses may cause some toxic effects. | | | |
| SECTION VII - PRECAUTIONS FOR SAFE HANDLING AND USE | | | |
| Steps to be Taken in Case Material is Released or Spilled Collect using commercially available mercury spill kit. Use kit's aspirator vacuum trap with a copper or copper-plated brush to sweep up excess mercury towards vacuum trap device. Wash spill area with dilute calcium sulfide or nitric acid solution. | | | |
| Preferred Waste Disposal Method Contact manufacturer or supplier for proper disposal methods. | | | |
| Precautions to be Taken in Handling and Storage Store in tightly closed containers in cool, dark, dry, well-ventilated area. Sources of ignition are prohibited where mercury is stored. Do NOT store on wood, porous floors, or unpainted metal shelves. | | | |
| Other Precautions and Warnings Outside or detached storage facility is recommended. Protect containers from physical damage. | | | |
| SECTION VIII - CONTROL MEASURES AND PERSONAL PROTECTIVE EQUIPMENT | | | |
| Respiratory Protection (<i>specify type</i>) Exposure levels are low. Use a respirator equipped with a fume filter. For best protection, use a supplied-air respirator with a full facepiece or an SCBA operated in positive pressure mode. | | | |
| Ventilation Local exhaust or general mechanical systems recommended. | | | |
| Protective Gloves Impervious Material | Eye Protection Chemical Goggles or Face Mask | Other Protective Clothing Protective Suit or Clothing | |
| Work/Hygiene Practices Always wash hands thoroughly after using chemical; never bring food, drink, or smoking materials into vicinity of chemicals. Skin contact must be avoided. | | | |

MERCURY

Hg

CAS: 7439-97-6

**IDENTIFICATION AND TYPICAL USES**

Mercury appears as a silver-colored, extremely heavy, odorless liquid metal. It is used in amalgams, as a catalyst, in electrical equipment, in cathodes for production of chlorine and caustic soda, in many different types of instruments (thermometers, barometers, thermostats), in mercury vapor lamps, in extractive metallurgy, in mirror coatings, arc lamps, boilers, and as a coolant and neutron absorber in nuclear power plants.

RISK ASSESSMENT: HEALTH**General Assessment**

Mercury is a toxic human poison by *inhalation* and dermal *absorption*. Mercury accumulates in the body with each exposure. While it is not currently listed as a carcinogen, human mutation data have been reported for mercury and its ability to cause cancer has been questioned. It is also an experimental teratogen and may cause adverse reproductive effects.

Symptoms of exposure by inhalation of mercury vapors can include sleeplessness, muscle weakness, anorexia, headaches, tinnitus, hypermotility, diarrhea, liver changes, dermatitis, and fever. Exposure to high levels can irritate the lungs, causing cough, tightness in chest, with possible progression to bronchitis, pneumonitis, and/or pulmonary edema (fluid in the lungs). Symptoms of pulmonary edema can be delayed up to 48 hours or more, thereby creating a false sense of security with regard to health exposure risk.

Skin contact can cause severe irritation if allowed to remain on the skin's surface. Skin absorption will occur and result in adverse nervous system effects.

Repeated exposure from inhalation, absorption, or both can cause central nervous system (CNS) effects including vertigo, anxiety, depression, ataxia, emotional instability, kidney injury, brain damage, tremors (the "shakes"), memory loss, metallic taste, discoloration of the skin, sore gums, personality changes, liver

damage, loose teeth, necrosis of the jaw, decreased urine excretion, visual disturbances and changes in eye lens color, and possible development of dermatitis.

☠ Acute Health Effects

The following acute (short-term) health effects may occur immediately or shortly after exposure to mercury:

Skin: Irritation, rash, dermatitis, and possible redness and the appearance of small blisters. Dermal absorption will cause toxic systemic effects.

Eye: Irritation, inflammation, watering, swelling, conjunctivitis.

Lung: Inhalation of mercury vapors may cause irritation of the mucous membranes in the respiratory tract causing cough, phlegm, and lung tissue irritation leading to bronchitis, pneumonitis, and even delayed pulmonary edema.

☘ Chronic Health Effects

The following chronic (long-term) health effects may occur at some time after exposure to mercury and can last for months or even years:

Cancer Hazards: According to the information presented in the references, mercury has not been adequately tested for its ability to cause cancer in test animals. However, human mutation data (causes genetic changes) have been documented and many scientists believe that such chemicals may pose a cancer risk in the long-term. More research is required.

Reproductive Hazards: According to information available in the references, mercury has been shown to cause cancer in test animals. There is limited evidence that mercury may cause an increase in spontaneous abortions in exposed women. Some organic

mercury compounds have been identified as human teratogens and can cause the early termination of pregnancies (miscarriages) and may injure the fetus. Mercury may also reduce fertility in both males and females. While inorganic mercury substances (those without carbon), have not specifically been shown to be human teratogens, they should still be handled with caution as they may cause reproductive problems in males and females.

Other Chronic Hazards: High or repeated exposure can cause kidney damage or mercury poisoning with symptoms of sore gums, "shakes" (especially noticeable in handwriting), irritability, increased saliva production, memory loss, extreme shyness, weakness, loss of teeth, poor appetite, and metallic taste. Serious personality changes and brain damage can occur, especially if exposure continues. Repeated skin contact may cause gray discoloration and a skin allergy may develop. If this happens, even small future exposures can cause rash. Repeated exposures may also cause reduced peripheral vision and brown staining of the eye. Mercury can accumulate in the body on prolonged exposure and it may take months or years for the body to dispose of excess mercury.

🔹 **Recommended Risk-Reduction Measures**

Personnel should avoid direct contact with mercury. Mercury is an extremely toxic, cumulative poison. If a less toxic chemical cannot be substituted for a hazardous material, then *engineering controls* are the most effective method of reducing exposures.

The best protection is to enclose operations and/or provide local exhaust ventilation at the site of chemical release. While not always operationally feasible, isolating operations can also reduce exposure. Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around mercury. Exposure levels for mercury are extremely low (0.1 mg/m^3) and difficult to monitor accurately. A full facepiece respirator with a high-efficiency particulate air (HEPA) filter equipped with a dust/mist/fume pre-filter may suffice. However, for the best protection use a supplied-air respirator with a full facepiece operated in positive pressure mode or an MSHA/NIOSH-approved self-contained breathing apparatus (SCBA) with full facepiece operated in pressure demand or other continuous flow mode. If a full facepiece is not available, then chemical/dust goggles should be worn to protect the eyes. Whenever a chemical dust hazard exists, a face shield and a protective apron should be worn. To pre-

vent hand and skin exposures, impervious rubber gloves should be used. Glove manufacturers should be contacted and permeation studies obtained *before* final glove selections are made. Mercury salts such as mercury are among mercury's most irritating and acutely toxic compounds. They are corrosive to skin tissues. Skin contact must be prevented.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with mercury dusts or solutions. All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where mercury is used or stored. Before first exposure and every six to twelve months thereafter, a complete medical history and examination is recommended, including the following:

- Examination of the nervous system (taking note of any problems with person's handwriting).
- Routine urinalysis and special urine test for mercury (should be less than 0.02 mg/liter).
- Eye examination.
- Lung function tests for frequent exposures.

If symptoms develop or overexposure is suspected, the above listed tests should be repeated, along with the following recommended tests:

- Consider nerve conduction tests.
- Urinary enzyme and neurological behavior tests.
- Serum mercury tests.
- Lung function tests.
- Consider chest X-ray following acute overexposure (may be negative if taken immediately after exposure due to delayed onset of pulmonary edema).

Any evaluation should include a careful history of past and present symptoms with a medical examination. Medical tests that look for damage already done are not a substitute for controlling exposure. Also, since smoking can cause heart disease, lung cancer, emphysema, and other respiratory disorders, smokers exposed to mercury may experience symptoms more rapidly than non-smokers under the same conditions of exposure. Other mixed exposures occur when personnel use creams to whiten or bleach the skin that contain mercury. If so, their use increases exposure

risk. Persons who are allergic to mercury may react to Mercurochrome or Merthiolate, which also contain mercury. Prudent risk management requires proper consideration of *all* exposure factors.

Other methods to reduce exposure include:

- ☑ Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not used, respiratory protection should be provided.
- ☑ Always ensure that proper protective clothing is worn when using chemical substances.
- ☑ Wash thoroughly immediately after exposure to mercury and at the end of the work shift or before eating, drinking, or smoking.
- ☑ Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of mercury should be communicated to all exposed workers.
- ☑ Eye wash stations and emergency showers should be located in the immediate work area.
- ☑ Work clothing that has been contaminated with mercury should never be worn home where family members can be exposed as well. Contaminated clothing should be laundered at work or by an authorized service by personnel who have been trained in the hazards associated with mercury.
- ☑ The drug n-acetyl penicillamine (NAP) has been used to treat mercury poisoning, with mixed success.
- ☑ Specific engineering controls are recommended for mercury by NIOSH. Refer to NIOSH Criteria Document, "Inorganic Mercury" (Publication Number 73-11024).

RISK ASSESSMENT: ENVIRONMENT

General Assessment

The environment is at risk of exposure during transportation, storage, disposal, or destruction of mercury. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance. Accidental spills of mercury, large or small, can result in fire, explosion, and possible contamination of the surrounding environmental mediums (water, soil, and air).

Mercury is incompatible with many common materials, including most metals (except iron). Reactions with oxidizers and acids can be vigorous and violent. These characteristics require special consideration during any emergency situation involving a leak or spill of mercury.

Elemental mercury is a heavy and relatively inert liquid which is oxidized to inorganic mercury (II) under natural conditions. Mercury (II) may combine with an organic fraction to form methyl mercury. Both mercury (II) and methyl mercury can cause environmental contamination. Mercury (II) may enter the environment in industrial or municipal waste treatment discharges, from previously contaminated sediments, and from the weathering of natural rocks. Bacteria may then convert it to methyl mercury. The concentration of mercury (II) in water may be elevated with acid rain due to the scouring of mercury from the air and increased partitioning from the sediment into the water.

☠ *Acute Ecological Effects*

Acute (short-term) toxic effects may include the death of animals, birds, or fish and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to mercury.

Mercury (II) and methyl mercury have high acute toxicity to aquatic life. Insufficient data are available to evaluate the short-term effects of mercury (II) and methyl mercury exposure to plants, birds, or terrestrial animals.

☪ *Chronic Ecological Effects*

Chronic (long-term) toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals.

Mercury (II) and methyl mercury have high chronic toxicity to aquatic life. Eating fish contaminated with mercury has caused secondary poisoning in humans. Birds or land animals similarly exposed to mercury and its compounds could also be subject to such effects. Insufficient data are available to evaluate the long-term effects of mercury exposure to plants.

◆ *Water Solubility*

Mercury is insoluble in water. Concentrations of 1 milligram will not mix with a liter of water.

Persistence in the Environment

Mercury is highly persistent in water, with a half-life greater than 200 days. The half-life of a pollutant is the amount of time it takes for one half of the chemical to be degraded. Mercury will volatilize rapidly when deposited in soil. When released into water, microorganisms convert mercuric salts into methyl mercury which is rapidly taken up by algae and enters the food chain. It concentrates in the edible tissues of fish and, eventually, can cause human poisoning as well.

Bioaccumulation in Aquatic Organisms

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans. The concentration of mercury and methyl mercury found in fish tissues is expected to be considerably higher than the average concentration in the water from which the fish was taken.

Recommended Risk-Reduction Measures

Proper training of all transporters will reduce the likelihood of a mishap or accidents resulting in a leak or spill to the environment. Proper labeling on all containers, trucks, and rail cars will enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

If a spill or leak to the environment has occurred, fire department, emergency response and/or hazardous materials spill personnel should be notified immediately. Do not dry sweep. Commercially available mercury spill cleanup kits should be considered. Otherwise, when vacuuming, a high-efficiency particulate air (HEPA) filter should be used, not a standard shop vacuum. Deposit collected materials in sealed drums for disposal. Cleanup should be attempted only by those trained in proper mercury spill containment procedures. Contaminated soils may need to be removed and replaced with clean soil. If mercury should contact the water table, aquifer, or navigable waterway, response activities should be prompt. When such spills occur, the local and/or state emergency response authorities should be notified. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of

mercury. If mercury is spilled or leaked, the following additional steps are recommended:

- Ventilate area and remove all ignition sources.
- It may be necessary to dispose of mercury as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving mercury can present a significant threat to business operations. The loss or damage of equipment or facilities can significantly affect fiscal viability. Lawsuits that may result from personnel injury/death, public exposures, and/or environmental contamination will also require a serious expenditure of resources. Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business. Always remember that anytime the term "reproductive hazard" is used, public emotion, hysteria, and ignorance can run equally high. This must be properly considered whenever developing public relations policies.

Recommended Risk-Reduction Measures

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of such procedures dealing with safety or emergency response. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

| Hazardous Components (specific identity) | | OSHA Exposure Criteria | NIOSH Exposure Criteria | Immediately Dangerous to Life and Health (IDLH) | ACGIH Exposure Criteria |
| Mesityl oxide (derivation: By dehydration of acetone or diacetone alcohol) 1 ppm = 4.08 mg/m³ | | PEL: 25 ppm 100 mg/m³ STEL: Not Established | REL: 10 ppm 40 mg/m³ STEL: Not Established | 1400 ppm | TLV: 15 ppm 60 mg/m³ STEL: 25 ppm 100 mg/m³ |
| SECTION III - PHYSICAL AND CHEMICAL CHARACTERISTICS | | | | | |
| Boiling Point 266°F (130°C) | | Specific Gravity (H ₂ O = 1) 0.86 | | | |
| Vapor Pressure (gas) 8 at 69°F (20°C) | | Molecular Weight 98.2 | | | |
| Vapor Density (Air = 1) 3.4 | | Melting Point -43°F (-41°C) | | | |
| Solubility Slightly soluble in water (3%). Soluble in alcohols, ethers, and with most organic liquids. | | | | | |
| Appearance and Odor Oily, colorless to light yellow liquid with a peppermint or honey-like odor. Odor Threshold = 12 ppm. | | | | | |
| SECTION IV - FIRE AND EXPLOSION HAZARD DATA | | | | | |
| Flash Point (method used) 87°F (31°C) closed cup | | Explosive Limits in Air % by Volume LEL: 1.4% UEL: 7.2% | | | |
| NFPA Classification Class IC Flammable Liquid | | Autoignition Temperature 652°F (344°C) | | | |
| Extinguishing Media Use alcohol foam, carbon dioxide, or dry chemical. Water spray or stream may spread fire. | | | | | |
| Special Fire Fighting Procedures Wear full protective clothing and self-contained breathing apparatus (SCBA). Poisonous gases are produced in fire. Use water spray to keep fire-exposed containers cool. Containers may explode in fire. | | | | | |
| Unusual Fire and Explosion Hazards Flammable liquid and a dangerous fire hazard when exposed to heat. At high temperatures, forms explosive mixtures with air. Violent reactions can occur with nitric acid. Chemical will react on contact with oxidizable materials. Moderate explosion hazard when in the form of vapor. Vapors are heavier than air and can travel for great distances to an ignition source and flashback to cause fire or explosion. | | | | | |

| SECTION V - REACTIVITY DATA | | | | |
|---|--|--|--|--|
| Stability | | Conditions to Avoid Normally stable. Keep away from sources of heat or flame. Large quantities should be stored in metal tanks or drums. Keep away from incompatible materials. | | |
| Stable X | Unstable | Incompatibility (<i>materials to avoid</i>) Strong oxidizers (permanganates, peroxides, nitrates, chlorates, and perchlorates), acids (nitric and sulfuric), strong alkalis, and amines. | | |
| Hazardous Polymerization | | Conditions to Avoid Under normal conditions of temperature and pressure, hazardous polymerization of mesityl oxide is not expected to occur. | | |
| May Occur | Will Not Occur X | Hazardous Decomposition or By-products When heated to decomposition, mesityl oxide can emit highly toxic/poisonous and acrid fumes and gases including oxides of carbon. | | |
| SECTION VI - HEALTH HAZARD DATA | | | | |
| Primary Route(s) of Entry: | | Inhalation? X | Absorption (skin)? | Ingestion? X |
| Health Hazards INHALATION: Symptoms include irritation of the eyes, nose, throat, and respiratory system. May cause depression of the central nervous system with narcosis, inebriation, headache, fatigue, malaise, and dizziness. Liver and kidney damage are also possible. Other effects include olfactory changes, faintness, dyspnea, vertigo, possible pulmonary edema, coma. SKIN & EYES: Irritating to the skin, may cause irritation and dermatitis. An eye irritant with possibility of corneal opacity and damage. INGESTION: Not a likely exposure route. Irritation of the mouth and stomach, narcosis, anesthesia. | | | | |
| Carcinogenicity Unknown Human Unknown Animal | NTP Listed? No | IARC Cancer Review Group? No | OSHA Regulated? 29 CFR 1910.1000 Table Z-1 | Target Organs? Respiratory system, eyes, skin, kidney, liver, CNS. |
| Medical Conditions Generally Aggravated by Exposure None reported. | | | | |
| Emergency and First-aid Procedures Eye contact: Flush immediately with water for 15 minutes (minimum); seek medical attention. Skin contact: Remove all contaminated clothing. Immediately wash area with large amounts of soap and water. Seek medical assistance. For inhalation: Remove the person from exposure. Provide respiratory assistance and CPR, if required. Transfer to medical facility. Observe for 24-48 hours for lungs effects. If swallowed: Seek medical attention immediately. Give large amounts of water or milk to dilute. Contact poison control center. Unless advised otherwise, do NOT induce vomiting (aspiration hazard). | | | | |
| SECTION VII - PRECAUTIONS FOR SAFE HANDLING AND USE | | | | |
| Steps to be Taken in Case Material is Released or Spilled Absorb in vermiculite or similar material and deposit in sealed containers. Ventilate area of spill. Restrict those not involved in cleanup from area. Remove all sources of ignition. Use non-sparking tools. | | | | |
| Preferred Waste Disposal Method Burn in chemical incinerator equipped with an afterburner and scrubber. | | | | |
| Precautions to be Taken in Handling and Storage Store to avoid contact with incompatible materials in tightly closed containers in cool, well-ventilated area away from heat and flame. Use only non-sparking tools to open and close containers. | | | | |
| Other Precautions and Warnings Sources of ignition are prohibited where mesityl oxide is used, handled, or stored. Heat may cause containers to build up pressure and explode. Containers must be grounded and bonded during transfer. | | | | |
| SECTION VIII - CONTROL MEASURES AND PERSONAL PROTECTIVE EQUIPMENT | | | | |
| Respiratory Protection (<i>specify type</i>) For exposures above the PEL, use an MSHA/NIOSH-approved organic vapor respirator, a supplied-air respirator with full facepiece, hood, or helmet in continuous flow mode, or use a self-contained breathing apparatus (SCBA) operated in pressure demand or other positive pressure mode. | | | | |
| Ventilation Local exhaust or general mechanical systems recommended. | | | | |
| Protective Gloves Impervious Material | Eye Protection Chemical Goggles or Face Mask | Other Protective Clothing Impervious Apron | | |
| Work/Hygiene Practices Always wash hands thoroughly after using chemical; never bring food, drink, or smoking materials into vicinity of chemicals. | | | | |

MESITYL OXIDE

CAS: 141-79-7

**IDENTIFICATION AND TYPICAL USES**

Mesityl oxide is an oily, colorless to light yellow liquid with a peppermint-like or honey-like odor. It is used as a solvent for cellulose ethers, vinyl resins, lacquers, roll-coating inks, and stains. It is also used in ore flotation, paint and varnish removers, insect repellent, and in the manufacture of methyl isobutyl ketone.

RISK ASSESSMENT: HEALTH**General Assessment**

Mesityl oxide is moderately toxic by *inhalation* and skin contact (dermal *absorption*). Ingestion is, of course, possible, but few reports exist documenting ingestion of mesityl oxide as a likely exposure route. Of the ketone compounds, mesityl oxide is considered to be among the most toxic in humans. Its carcinogenicity, mutagenicity, and teratogenicity in humans have not been reported.

Inhalation can cause changes in the sense of smell, conjunctiva irritation, and possible respiratory changes. It will irritate the nose, throat, and eyes and fatigue the sense of smell. It may also cause a dangerous buildup of fluid in the lungs (pulmonary edema) which is a medical emergency and can be fatal. Symptoms can be delayed up to 48 hours, thereby creating a false sense of security with regard to health exposure risk. Mild to severe narcotic properties have also been recorded, including pronounced headache and depression of the central nervous system. Other symptoms on inhalation and CNS depression include nausea, dizziness, fatigue, malaise, narcosis, vertigo, dyspnea, decreased breathing rate, and anesthesia. Kidney and liver damage with mild narcosis may also be possible.

Skin and eye contact may produce mild to moderate irritation on contact. Pure liquid in contact with

the eye may result in corneal opacity and subsequent damage. Skin contact can cause defatting, dryness, cracking, and dermatitis. First and even second degree burns are possible on prolonged contact.

On ingestion, mesityl oxide is expected to produce symptoms of irritation of the mouth and stomach, nausea, vomiting, stomach pain, narcosis, and anesthesia.

☠ Acute Health Effects

The following acute (short-term) health effects may occur immediately or shortly after exposure to mesityl oxide:

- Skin:** Will defat the skin and can cause dermatitis. Pure liquid will cause severe irritation and even first or second degree burns.
- Eye:** Severe irritation with a potential for corneal injury or damage.
- Lung:** Nose and throat irritation. Produces intoxicating effects and may cause lung damage, including pulmonary edema.
- CNS:** There may be depression, anesthesia, hypothermia, narcosis, and other effects.

☘ Chronic Health Effects

The following chronic (long-term) health effects may occur at some time after exposure to mesityl oxide and can last for months or even years:

Cancer Hazards: According to information presented in the references, mesityl oxide has not been adequately tested for its ability to cause cancer in test animals.

Reproductive Hazard: According to information presented in the references, mesityl oxide has not been adequately tested for its ability to adversely affect reproduction.

Other Chronic Effects: Prolonged skin contact may cause drying, cracking, and chapping of the affected area. There may be skin sensitization and/or dermatitis in some individuals. Repeated or long-term exposures to mesityl oxide may affect the liver and kidneys.

🔹 **Recommended Risk-Reduction Measures**

Personnel should avoid direct contact with mesityl oxide. Of the ketones, mesityl oxide is among the most toxic. If a less toxic chemical cannot be substituted for a hazardous substance, then *engineering controls* are the most effective method of reducing exposures. The best protection is to enclose operations and/or provide local exhaust ventilation at the site of chemical release. While not always operationally feasible, isolating operations can also reduce exposure. Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around mesityl oxide. It is irritating at levels above 15 ppm and an organic vapor respirator should always be used to ensure exposure control. For exposures above the 25-ppm PEL, a supplied-air respirator with full facepiece operated in continuous flow mode, or a self-contained breathing apparatus (SCBA) with full facepiece operated in pressure demand are the recommended respiratory protection methods of choice. If a full facepiece is not available, then chemical goggles should be worn to protect the eyes. Whenever a chemical splash hazard exists, a face shield and a rubber apron should be worn. To prevent hand and skin exposures, impervious gloves should be used. Glove manufacturers should be contacted and permeation studies obtained *before* final glove selections have been made.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with mesityl oxide.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where mesityl oxide is used or stored.

If symptoms develop or overexposure is suspected, the following tests are recommended:

- ☑ Kidney and liver function tests.

- ☑ Evaluation by a qualified allergist, with careful consideration of exposure history and special skin tests (may help diagnose allergy).
- ☑ Lung function tests.
- ☑ Consider chest X-ray following acute overexposure (may be negative if taken immediately after exposure due to delayed onset of pulmonary edema).

Any evaluation should include a careful history of past and present symptoms with an examination. Medical tests that simply look for existing damage are not a substitute for controlling exposures. Also, since smoking can cause heart disease, emphysema, and other respiratory disorders, symptoms of exposure to mesityl oxide may be more pronounced than those displayed by non-smokers. Proper risk assessment requires careful consideration of *all* possible factors that may be causing the appearance of symptoms in exposed workers.

Other methods to reduce exposure include:

- ☑ Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not used, respiratory protection should be mandatory. Also, if possible, automatic transfer of mesityl oxide from storage containers to process or work containers is recommended.
- ☑ Always ensure that proper protective clothing is worn when using chemical substances.
- ☑ Wash thoroughly immediately after exposure to mesityl oxide and at the end of the work shift or before eating, drinking, or smoking.
- ☑ Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of mesityl oxide should be communicated to all exposed and potentially exposed workers.
- ☑ Eye wash stations should be provided in the immediate work area for emergency use. If there is a possibility of skin exposure to mesityl oxide, emergency shower facilities should also be provided in the immediate work area.
- ☑ Personnel should never wear contaminated clothing home (family members can be exposed). Clothing should be laundered by personnel who have been trained on the hazards of mesityl oxide.

RISK ASSESSMENT: ENVIRONMENT**General Assessment**

The environment is at risk of exposure and contamination during transportation, storage, disposal, or destruction of mesityl oxide. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance. Accidental spills, large or small, can result in fire, explosion, and possible contamination of the surrounding environmental mediums (water, soil, and air).

Mesityl oxide is considered a Class IC flammable liquid (per OSHA 29 CFR 1910.106). It presents a moderate fire and explosion hazard risk, especially in contact with incompatible materials. These characteristics require extreme caution in handling, storage, transportation, and disposal. It is incompatible with common peroxides and other oxidizers and contact can cause fire or explosion. It reacts violently when added to nitric or sulfuric acid. Therefore, special consideration is required during any emergency situation involving a leak or spill of mesityl oxide. Should mesityl oxide ever come into contact with these or other incompatible substances during use, transportation, storage, or disposal, the formation of highly toxic and/or highly explosive commodities is extremely possible.

The proper disposal method for mesityl oxide is to burn it in a chemical incinerator equipped with an afterburner and scrubber.

Mesityl oxide may enter the environment through industrial discharges or spills.

☠ Acute Ecological Effects

Acute (short-term) toxic effects may include the death of animals, birds, or fish and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to mesityl oxide.

Insufficient data are available on the short-term effects of mesityl oxide exposure to aquatic life, birds, plants, or land animals.

🕒 Chronic Ecological Effects

Chronic (long-term) toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals.

Insufficient data are available on the long-term effects of mesityl oxide exposure to aquatic life, birds, plants, or land animals.

💧 Water Solubility

Mesityl oxide is nearly insoluble in water. Concentrations of less than 100 milligrams may mix with a liter of water, depending on water pH and chemical concentration of mesityl oxide.

🕒 Persistence in the Environment

Mesityl oxide is moderately persistent in water, with a half-life between 20 and 200 days. The half-life of a pollutant is the amount of time it takes for one half of the chemical to be degraded.

🐟 Bioaccumulation in Aquatic Organisms

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans.

The concentration of mesityl oxide found in fish tissue is expected to be somewhat higher than the average concentration of mesityl oxide in the water from which the fish was taken.

🛡 Recommended Risk-Reduction Measures

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in a leak or spill to the environment. The correct use of DOT labeling (per the MSDS) on all containers, trucks, and rail cars will enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of mesityl oxide should be segregated from incompatible chemicals to minimize the risk of cross-contamination or contact. Buildings designated for storage should be equipped with appropriate fire protection systems (alarms, sprinklers, emergency lighting, portable extinguishers).

If a spill or leak to the environment has occurred, fire department, emergency response and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those trained in proper spill containment procedures using non-sparking tools. Contaminated soils should be removed for incineration and replaced with clean soil. If mesityl oxide should contact the water table, aquifer, or navigable waterway, cleanup should be started immediately. It is only slightly soluble in water and total remediation may be possible. The local and/or state emergency response authorities must be notified. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to

Risk Management for Hazardous Chemicals

any operations involving the use, transportation, storage, or disposal of mesityl oxide. If mesityl oxide is spilled or leaked, the following specific steps are recommended:

- ☑ Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened for normal work.
- ☑ Remove all ignition sources, ventilate area of leak.
- ☑ Absorb liquids in vermiculite, dry sand, earth, or similar material and deposit in sealed containers using non-sparking tools.
- ☑ It may be necessary to dispose of mesityl oxide as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving mesityl oxide can present a significant threat to business operations. The loss or damage of equipment or facilities can significantly affect fiscal viability. Lawsuits that may result from personnel injury/death, public exposures, and/or environmental contamination will also require a serious expenditure of resources. Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business.

Recommended Risk-Reduction Measures

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures dealing with safety or emergency response. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

| May Occur X | Will Not Occur | Hazardous Decomposition or By-products When heated to decomposition, methacrylic acid can emit highly toxic/poisonous gases, including carbon monoxide and acrid fumes. | | |
| SECTION VI - HEALTH HAZARD DATA | | | | |
| Primary Route(s) of Entry: | | Inhalation? X | Absorption (skin)? X | Ingestion? X |
| Health Hazards INHALATION: Causes irritation to the eyes, nose, throat, and respiratory system. Other effects include headache, nausea, vomiting, confusion, dizziness, and loss of consciousness. Chronic exposure can lead to bronchospasm and wheezing. ABSORPTION: Skin contact results in irritation and burns. Causes severe eye burns and/or irritation. Absorbed methacrylic acid is rapidly metabolized as a short chain fatty acid. Possible skin sensitizer. Corrosive to skin. Chronic exposure can lead to dermatitis. INGESTION: Poisonous by ingestion. Gastrointestinal irritation with unspecified systemic effects. | | | | |
| Carcinogenicity Unknown Human Unknown Animal | NTP Listed? No | IARC Cancer Review Group? No | OSHA Regulated? 29 CFR 1910.1000 Table Z-1 | Target Organs? Respiratory system, eyes, skin. |
| Medical Conditions Generally Aggravated by Exposure Respiratory impairments (bronchitis, asthma) or skin conditions (dermatitis) may be aggravated. | | | | |
| Emergency and First-aid Procedures <u>Eye contact:</u> Flush immediately with water for 15 minutes (minimum); seek medical attention. <u>Skin contact:</u> Remove all contaminated clothing. Immediately wash area with large amounts of soap and water. <u>Seek medical assistance.</u> For <u>inhalation:</u> Remove the person from exposure. Provide respiratory assistance and CPR. Transfer to medical facility. If <u>swallowed:</u> Seek medical attention. Give 1 to 2 glasses of water to dilute. Never give an unconscious or convulsing person anything by mouth. | | | | |
| SECTION VII - PRECAUTIONS FOR SAFE HANDLING AND USE | | | | |
| Steps to be Taken in Case Material is Released or Spilled Absorb liquids in vermiculite or similar material and deposit in sealed containers. Ventilate area of spill or leak. Restrict those not involved in cleanup from entering area. Spills can be neutralized with crushed limestone, soda ash, or lime. Non-sparking tools should be used during cleanup. | | | | |
| Preferred Waste Disposal Method Incineration (with afterburner and scrubber). | | | | |
| Precautions to be Taken in Handling and Storage To keep stable, store in cool (below 59°F), dry, well-ventilated area away from heat. Protect containers from physical damage. Storage in separate facility is recommended. Keep out of direct sunlight. | | | | |
| Other Precautions and Warnings Sources of ignition are prohibited where methacrylic acid is used, handled, or stored. | | | | |
| SECTION VIII - CONTROL MEASURES AND PERSONAL PROTECTIVE EQUIPMENT | | | | |
| Respiratory Protection (<i>specify type</i>) When potential for high exposures (above 20 ppm) exist, use an MSHA/NIOSH-approved supplied-air respirator with full facepiece, hood, or helmet in continuous flow mode, or use a full facepiece operated in pressure demand or other positive pressure mode. Use half-mask respirator with acid cartridge for low or transient exposures (cartridge should be designed to protect against acid vapor or mist). | | | | |
| Ventilation Local exhaust or general mechanical systems recommended. | | | | |
| Protective Gloves Acid resistant synthetic rubber | Eye Protection Chemical Goggles or Face Mask | Other Protective Clothing Protective Rubber Apron | | |
| Work/Hygiene Practices Always wash hands thoroughly after using chemical; never bring food, drink, or smoking materials into vicinity of chemicals. | | | | |

isolating operations can also reduce exposure. Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around methacrylic acid. A powered, air-supplied respirator or a self-contained breathing apparatus (SCBA) with full facepiece operated in pressure demand or other positive pressure mode is the recommended respiratory protection of choice. If a full facepiece is not available, then chemical goggles should be worn to protect the eyes. For low concentrations (below 20 ppm), an acid gas cartridge respirator (equipped with a mist/vapor filter) is acceptable protection. Whenever a chemical splash hazard exists, a face shield and a rubber apron should be worn. To prevent hand and skin exposures, acid resistant gloves should be used. Glove manufacturers should be contacted and permeation studies obtained *before* final glove selections have been made.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with methacrylic acid.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where methacrylic acid is used or stored. Other methods to reduce exposure include:

- ☑ Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not used, respiratory protection should be mandatory.
- ☑ Always ensure that proper protective clothing is worn when using chemical substances.
- ☑ Wash thoroughly immediately after exposure to methacrylic acid and at the end of the work shift or before eating, drinking, or smoking.
- ☑ Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of methacrylic acid should be communicated to all exposed or potentially exposed workers.

RISK ASSESSMENT: ENVIRONMENT

General Assessment

The environment is at risk of exposure during transportation, storage, disposal, or destruction of meth-

acrylic acid. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance. Accidental spills, large or small, can result in fire, explosion, and possible contamination of the surrounding environmental mediums (water, soil, and, to a lesser degree, air).

Methacrylic acid is considered a class IIIA combustible liquid (per OSHA 29 CFR 1910.106). However, its vapors can form explosives mixtures especially in confined or enclosed spaces. It is also incompatible with oxidizing agents and strong acid. Contact with either can cause violent reactions, including fire or explosion. These characteristics require special consideration during any emergency situation involving a leak or spill of methacrylic acid.

Should methacrylic acid ever come into contact with incompatible substances such as oxidizers, acid, or even elevated temperatures either during use, transportation, or storage, the formation of highly toxic and/or highly explosive commodities is extremely possible.

The proper disposal/destruction method for methacrylic acid waste is to burn it in a chemical incinerator equipped with an afterburner and air scrubber.

Methacrylic acid can enter the environment mainly industrial discharges or spills.

☠ *Acute Ecological Effects*

Acute (short-term) toxic effects may include the death of animals, birds, or fish and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to methacrylic acid.

Insufficient data are available to evaluate or predict the short-term effects of methacrylic acid exposure to aquatic life, plants, birds, or land animals.

🕒 *Chronic Ecological Effects*

Chronic (long-term) toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals.

Insufficient data are available to evaluate or predict the long-term effects of methacrylic acid to aquatic life, plants, birds, or land animals.

💧 *Water Solubility*

Methacrylic acid is highly soluble in water. Concentrations of 1000 milligrams and more will mix with a liter of water.

🕒 *Persistence in the Environment*

Methacrylic acid is slightly persistent in the aquatic environment, with a half-life of between 2 to 20 days. The half-life of a pollutant is the amount of time it takes for one half of the chemical to be degraded.

Approximately 90% of methacrylic acid will eventually end up in water; the remainder will end up in air.

🌊 Bioaccumulation in Aquatic Organisms

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans.

The concentration of methacrylic acid found in fish tissues is expected to be about the same as the average concentration of methacrylic acid in the water from which the fish was taken.

🔍 *Recommended Risk-Reduction Measures*

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in a leak or spill to the environment. The correct use of DOT labeling (per the MSDS) on all containers, trucks, and rail cars will enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of methacrylic acid should be segregated from incompatible chemicals to minimize the risk of cross-contamination or contact. Buildings designated for storage should be equipped with appropriate fire protection systems (alarms, sprinklers, emergency lighting, portable extinguishers).

If a spill or leak to the environment has occurred, fire department, emergency response and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those trained in proper spill containment procedures using non-sparking tools. Contaminated soils should be removed for incineration and replaced with clean soil. If methacrylic acid should contact the water table, aquifer, or navigable waterway, time is of the essence. It is highly miscible in water and, therefore, total containment and remediation may not be possible. When such spills occur, the local and/or state emergency response authorities must be notified. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of methacrylic acid. If methacrylic acid is

spilled or leaked, the following specific steps are recommended:

- ☑ Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened for normal work.
- ☑ Remove all ignition sources, ventilate area.
- ☑ Absorb liquids in vermiculite, dry sand, earth, or similar material and deposit in sealed containers. Spilled materials can be neutralized using crushed limestone, soda ash, or lime.
- ☑ It may be necessary to dispose of methacrylic acid as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving methacrylic acid can present a significant threat to business operations. The loss or damage of equipment or facilities can significantly affect fiscal viability. Lawsuits that may result from personnel injury/death, public exposures, and/or environmental contamination will also require a serious expenditure of resources. Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business.

🔍 *Recommended Risk-Reduction Measures*

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures dealing with safety or emergency response. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

| 1 | 4 | 0 | | 0 = Minimum Hazard 1 = Slight Hazard 2 = Moderate Hazard 3 = Serious Hazard 4 = Severe Hazard | HEALTH = BLUE FIRE = RED REACTIVITY = YELLOW OTHER = WHITE | OX = Oxidizer ACID = Acid ALK = Alkali COR = Corrosive W = Use No Water |

SECTION I - GENERAL INFORMATION

| | | |
|--|--|------------------------------------|
| Characterization Gas, Hydrocarbon | RCRA Number None | EPA Class Not Applicable |
| DOT Proper Shipping Name Methane, Compressed or Methane, Refrigerated Liquid | Chemical Abstract Service (CAS) Number 74-82-8 | |
| DOT Hazard Class and Label Requirements Flammable Gas (both forms) | DOT Emergency Guide Code 15 | |
| DOT Identification Number UN 1971 (compressed); UN 1972 (liquid) | Chemical Formula CH₄ | |

Synonyms
Fire damp; marsh gas; methyl hydride.

SECTION II - HAZARDOUS INGREDIENTS AND IDENTITY INFORMATION

| Hazardous Components (specific identity) | OSHA Exposure Criteria | NIOSH Exposure Criteria | Immediately Dangerous to Life and Health (IDLH) | ACGIH Exposure Criteria |
|---|---|---|---|---|
| Methane (derivation: From natural gas by absorption or adsorption; from coal mines for use as fuel gas; from a mixture of carbon monoxide and hydrogen (synthesis gas) obtained by reaction of hot coal with steam, the mixed gas is passed over a nickel-based catalyst at high temperature). | PEL: Not Established STEL: Not Established | REL: Not Established STEL: Not Established | Not Determined | TLV: Not Established STEL: Not Established |

SECTION III - PHYSICAL AND CHEMICAL CHARACTERISTICS

| | |
|---|--|
| Boiling Point -259°F (-167°C) | Specific Gravity (H ₂ O = 1) .926 |
| Vapor Pressure (atmospheres) Not Found | Molecular Weight 16.05 |
| Vapor Density (Air = 1) 0.6 at 32°F (0°C) | Freezing Point -296°F (-182°C) |

Solubility
Only slightly soluble in water. Soluble in alcohol and ether.

Appearance and Odor
Colorless, odorless, tasteless gas.

SECTION IV - FIRE AND EXPLOSION HAZARD DATA

| | |
|--|--|
| Flash Point (method used) -213°F (-136°C) closed cup | Explosive Limits in Air % by Volume LEL: 5% UEL: 15% |
| NFPA Classification Flammable Gas | Autoignition Temperature 999°F (537°C) |

Extinguishing Media
Stop flow of gas to stop fire. If this is not possible, letting fire burn itself out may be only alternative.

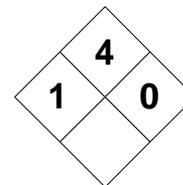

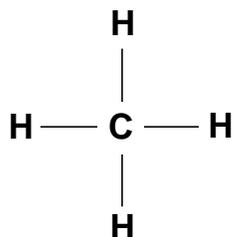

Special Fire Fighting Procedures
Methane is an extremely flammable, very dangerous fire and explosion hazard. Poisonous gases are evolved from fire. Wear a self-contained breathing apparatus (SCBA) with full facepiece. Ensure ALL sources of escaping gas are controlled. Monitor area long after fire is extinguished. Move containers from fire area if it can be done without risk. Use water spray to cool fire-exposed containers.

Unusual Fire and Explosion Hazards
Gas is explosive. Containers may explode in flame. Even if fire is extinguished, escaping gas can form explosive mixtures in air quickly and ignite without warning.

| SECTION V - REACTIVITY DATA | | | | |
|---|----------------------------|--|------------------------------|---|
| Stability | | Conditions to Avoid Methane is normally stable in its closed containers, during routine operations (those that do not expose it to ignition sources). Avoid contact with heat, sparks, flame, lighted tobacco products, and steam lines. | | |
| Stable X | Unstable | Incompatibility (materials to avoid) Methane is reactive in contact with chlorine or chlorine dioxide, bromine pentafluoride, nitrogen trifluoride, liquid oxygen, oxygen difluoride, other oxidizers, heat, sparks, and open flame. | | |
| Hazardous Polymerization | | Conditions to Avoid Under normal conditions of temperature and pressure, hazardous polymerization of methane is not expected to occur. | | |
| May Occur | Will Not Occur X | Hazardous Decomposition or By-products If involved in fire, methane can produce toxic oxides of carbon (carbon monoxide and carbon dioxide). | | |
| SECTION VI - HEALTH HAZARD DATA | | | | |
| Primary Route(s) of Entry: | | Inhalation? X | Absorption (skin)? | Ingestion? |
| Health Hazards INHALATION: An asphyxiant gas. Initial symptoms are those of oxygen starvation. Feeling of "air hunger," diminished mental alertness, headache, dullness, shortness of breath, and an impairment in muscle coordination. Continued exposures lead to faulty judgment, depression of senses, rapid fatigue, unconsciousness, convulsions, coma, and death. SKIN & EYES: Contact with the compressed gas or refrigerated liquid can cause frostbite and burns. INGESTION: Not likely since methane is a gas at normal working (room) temperatures. | | | | |
| Carcinogenicity Unknown Human Unknown Animal | NTP Listed? No | IARC Cancer Review Group? No | OSHA Regulated? No | Target Organs? None Reported |
| Medical Conditions Generally Aggravated by Exposure None Reported. | | | | |
| Emergency and First-aid Procedures Eye contact: Immediately flush with large amounts of warm (tepid) water for 15 minutes (minimum), occasionally lifting eyelids; seek medical attention. Skin contact: Remove all contaminated clothing. Immediately wash area with large amounts of warm (tepid) water. Do NOT rub or use air-blown heat on affected area. For inhalation: Remove the person from exposure. Provide respiratory assistance and CPR. Transfer promptly to medical facility. If swallowed: Not likely. | | | | |
| SECTION VII - PRECAUTIONS FOR SAFE HANDLING AND USE | | | | |
| Steps to be Taken in Case Material is Released or Spilled Remove all ignition sources. Ventilate area. Stop flow of gas. If the source of leak is a cylinder and cannot be stopped, remove to safe place in open air; repair leak or let cylinder empty. If gas has not yet ignited, use a water spray to knock down vapors and direct them from ignition source. | | | | |
| Preferred Waste Disposal Method None specified in the references (incineration of a gas may be the only alternative). | | | | |
| Precautions to be Taken in Handling and Storage Do not store with incompatible materials or in the presence of heat since violent reactions or explosions can occur. Store in tightly closed pressurized containers in a cool, dark, well-ventilated area away from sunlight. Keep away from ignition sources such as fire, sparks, and flame. | | | | |
| Other Precautions and Warnings Bulk storage of methane is not recommended. Containers may explode in fire or under conditions of extreme heat (do not store outdoors or in direct sunlight). | | | | |
| SECTION VIII - CONTROL MEASURES AND PERSONAL PROTECTIVE EQUIPMENT | | | | |
| Respiratory Protection (specify type) No exposure limits have been established. Methane is a simple asphyxiant. Do NOT use cartridge-type respirators (ineffective for this type of gas). Use a powered supplied-air respirator or a self-contained breathing apparatus with full facepiece operated in pressure demand or other positive pressure mode. | | | | |
| Ventilation Local exhaust or general mechanical systems recommended. | | | | |
| Protective Gloves Insulated Rubber | | Eye Protection Goggles and/or Face Mask | | Other Protective Clothing Leather Apron |
| Work/Hygiene Practices Always wash hands thoroughly after using chemical; never bring food, drink, or smoking materials into vicinity of chemicals. | | | | |

METHANECH₄

CAS: 74-82-8

**IDENTIFICATION AND TYPICAL USES**

Methane is a colorless, tasteless, and odorless gas. It is used as a source of petrochemicals by conversion to hydrogen and carbon monoxide by steam cracking or partial oxidation. Products derived from methane include methanol, acetylene, hydrogen cyanide, and ammonia. As a natural gas, methane is used as a fuel, as a source of carbon black, and as the starting material for the manufacture of synthetic proteins.

RISK ASSESSMENT: HEALTH**General Assessment**

Methane is a simple asphyxiant gas. As such, its primary route of entry into the body is through *inhalation*. While it does not pose a significant physiological effect (i.e., no systemic poisoning or toxicity), it can displace oxygen levels to below that which is necessary to sustain life. Skin contact with the liquid can be destructive to tissues due to the extremely cold temperatures but absorption is not a likely exposure route. Since methane usually exists as a gas at room temperatures, ingestion is not likely to occur either. It is not known to cause cancer, mutations, or reproductive effects in humans or test animals. It is an asphyxiant.

Inhalation of methane gas can cause headache, dullness, shortness of breath, and the symptoms of asphyxiation. These include rapid respiration and a feeling of "air hunger" or air starvation followed by a decrease in mental alertness, and impaired muscular coordination. If exposure continues, there can be nausea, vomiting, prostration, unconsciousness, coma, and death.

Skin or eye contact with the vapor poses no serious threat. The vapors have not been shown to cause any physiological response. However, if the liquid should contact either the skin or the eyes, there can be serious irritation, burns, tissue damage, and frostbite.

☠ Acute Health Effects

The following acute (short-term) health effects may occur immediately or shortly after exposure to methane:

Skin: Liquid threat only. Redness, pain, swelling, blisters, and severe frostbite.

Eye: Liquid threat only. Causes frostbite, redness, irritation, severe pain, and blurred vision.

Lung: Vapor is non-irritating and therefore poses no threat of damage to the lungs. However, in high concentrations, methane can lead to symptoms of asphyxiation and oxygen deprivation up to and including death.

☪ Chronic Health Effects

The following chronic (long-term) health effects may occur at some time after exposure to methane and can last for months or even years:

Cancer Hazards: According to information presented in the references, exposure to methane does not lead to carcinogenic effects (it is a simple asphyxiant).

Reproductive Hazards: There are no reports to support any claims of reproductive hazards.

Other Chronic Effects: None reported.

🛡 Recommended Risk-Reduction Measures

Personnel should avoid direct contact with methane. If another gas cannot be substituted for a methane, then *engineering controls* are the most effective method of reducing exposures. The best protection is to separate operations and provide local, explosion-proof exhaust ventilation at the site of chemical release. While not always operationally feasible, isolating operations can also reduce exposure. Using equipment with explosion-proof designs and ensuring all metal containers and tools are electrically grounded

and bonded can further reduce the potential for injury or damage. Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with methane. Air-purifying respirators (e.g., the cartridge-type or gas masks) cannot be used with methane. These type respirators only purify the air and can do nothing to protect in oxygen deficient atmospheres. A powered air-supplied respirator operated in pressure demand or other positive pressure mode, or a self-contained breathing apparatus (SCBA) with full facepiece operated in pressure demand mode are the recommended respiratory protection methods of choice. If a full facepiece is not available, then chemical goggles should be worn to protect the eyes. Whenever a chemical splash hazard exists, a face shield and a rubber or leather apron should be worn. To prevent hand and skin exposures with the liquid, thermal protective gloves should be used.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with methane.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where methane is used or stored.

Other methods to reduce exposure to chemicals include:

- ☑ Where possible, consider installing automatic sensors that warn personnel of dropping oxygen levels and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not used, respiratory protection should be mandatory.
- ☑ Always ensure that proper protective clothing is worn when using chemical substances and that personnel have been trained in its use, care, and maintenance.
- ☑ Wash thoroughly immediately after exposure to methane and at the end of the work shift or before eating, drinking, or smoking.
- ☑ Safety shower and eyewash stations should be readily available in work areas where methane is used or stored.
- ☑ Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information

on the health and safety hazards of methane should be communicated to all exposed or potentially exposed workers.

RISK ASSESSMENT: ENVIRONMENT

General Assessment

The environment is at risk of exposure during transportation, storage, disposal, or destruction of methane. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance. Accidental releases, large or small, can result in fire, explosion, and possible contamination of the surrounding environmental mediums (water, soil, and air). Methane is an extremely flammable and highly explosive gas. Its extremely low flash point and boiling point present a serious fire hazard. It has a relatively wide flammability range in air. Also, since it can react violently in the presence of oxidizers, such as chlorine, methane requires special consideration during any emergency involving a leak or release of methane gas or liquid.

Methane can enter the environment through industrial discharges, unchecked venting to air, or through spills of the liquid. Since liquids will most likely vaporize rapidly, water and soil contamination are possible but not probable.

☠ *Acute Ecological Effects*

Acute (short-term) toxic effects may include the death of animals, birds, or fish, and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to methane.

Insufficient data are available on the short-term effects of methane on aquatic life, plants, birds, or land animals. However, as a relatively non-toxic, simple asphyxiant, it might be assumed that ecological toxicity will be relatively low.

●* *Chronic Ecological Effects*

Chronic (long-term) toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals.

Insufficient data are available to evaluate the long-term effects of methane to aquatic life, plants, birds, or land animals. However, as a relatively non-toxic, simple asphyxiant, it might be assumed that any chronic ecological toxicity will be relatively low.

💧 **Water Solubility**

Methane is only slightly soluble in water. Concentrations of 1 milligram will mix with a liter of water.

🕒 **Persistence in the Environment**

Methane is non-persistent in water, with a half-life of less than 2 days. The half-life of a pollutant is the amount of time it takes for one half of the chemical to be degraded. Virtually 100% of methane will eventually end up in the air.

🐟 **Bioaccumulation in Aquatic Organisms**

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans.

Methane is not expected to accumulate in the tissues of fish.

🛡️ **Recommended Risk-Reduction Measures**

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in a leak or release to the environment. The correct use of DOT labeling (per the MSDS) on all containers, trucks, and rail cars will enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of methane should be segregated from incompatible chemicals to minimize the risk of cross-contamination or contact. Buildings designated for storage should be equipped with appropriate fire protection systems (alarms, sprinklers, emergency lighting, portable extinguishers).

If a spill or release to the environment has occurred, fire department, emergency response, and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those trained in proper containment procedures using non-sparking tools. Contaminated soils should be removed for incineration and replaced with clean soil. When spills or leaks occur, it may be necessary to contact the local and/or state emergency response authorities. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of methane. If methane is spilled or leaked, the following specific steps are recommended:

- ☑️ Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened for normal work.
- ☑️ Remove ignition sources, and ventilate area
- ☑️ If applicable, stop flow of leaking liquid or gas. If leak source is a cylinder and the leak cannot be stopped in place, remove leaking cylinder to a safe place in the open air, and allow cylinder to empty.
- ☑️ Keep methane out of a confined space, such as a sewer, because of the possibility of explosion (unless the sewer is designed to prevent the buildup of explosive concentrations).
- ☑️ It may be necessary to dispose of methane as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving methane can present a significant threat to business operations. The loss or damage of equipment or facilities can significantly affect fiscal viability. Lawsuits that may result from personnel injury, public exposures, and environmental contamination will also require a serious expenditure of resources. Media attention surrounding an injury, illness, or environmental damage can also result in a loss of profits and loss of current as well as future business.

🛡️ **Recommended Risk-Reduction Measures**

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures dealing with safety and emergency response. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

High levels can lead to seizures, loss of consciousness, and death. Kidney and liver damage probable. ABSORPTION: Will pass through unbroken skin and enter the bloodstream. Contact may severely irritate the skin and eyes. Systemic effects dominated by somnolence and depression. INGESTION: Poisonous to humans by ingestion. Systemic effects due to central nervous system action include tremors, convulsion, excitement, ataxia, and gastritis. | | | | |
| Carcinogenicity Questioned Human Suspected Animal | NTP Listed? No | IARC Cancer Review Group? Group 3 | OSHA Regulated? 29 CFR 1910.1000 Table Z-1 | Target Organs? Skin, CNS, liver, kidney, reproductive system. |
| Medical Conditions Generally Aggravated by Exposure Kidney and liver diseases, and convulsive disorders may be aggravated by exposure. | | | | |
| Emergency and First-aid Procedures Eye contact: Do not allow victim to keep eyes tightly shut. Flush immediately with water for 15 minutes; seek medical attention. Skin contact: Remove all contaminated clothing. Immediately wash area with flooding amounts of water, then triple-wash with soap and water. Inhalation: Remove the person from exposure. Provide respiratory assistance and CPR. Transfer to medical facility. If swallowed: Contact poison control center. Unless advised otherwise and victim is conscious, give 1-2 glasses of water. The decision to induce vomiting must be carefully considered since CNS depression may induce seizures. Seek medical attention. Never give anything by mouth to an unconscious or convulsing person. | | | | |
| SECTION VII - PRECAUTIONS FOR SAFE HANDLING AND USE | | | | |
| Steps to be Taken in Case Material is Released or Spilled Remove all sources of heat. Ventilate area of spill. Restrict those not involved in cleanup from entering area. Notify appropriate authorities. Collect powder materials using HEPA vacuum. Do NOT dry sweep. Absorb any liquid solution spills in vermiculite and place in sealed drum for disposal. | | | | |
| Preferred Waste Disposal Method No citation. | | | | |
| Precautions to be Taken in Handling and Storage Store in tightly closed containers in cool, dry, dark, well-ventilated area away from heat. | | | | |
| Other Precautions and Warnings Avoid generating dusty conditions in storage areas. Protect containers from physical damage. | | | | |
| SECTION VIII - CONTROL MEASURES AND PERSONAL PROTECTIVE EQUIPMENT | | | | |
| Respiratory Protection (<i>specify type</i>) For exposures above 15 mg/m³ for extended periods, use a NIOSH-approved supplied-air respirator or a self-contained breathing apparatus (SCBA) with full facepiece operated in positive pressure mode. | | | | |
| Ventilation Local exhaust (preferred) at site of chemical work or general ventilation. | | | | |
| Protective Gloves Polycarbonate or Butyl Rubber | Eye Protection Chemical/Dust Goggles or Face Mask | Other Protective Clothing Protective Apron, Boots (avoid skin contact) | | |
| Work/Hygiene Practices Always wash hands thoroughly after using chemical; never bring food, drink, or smoking materials into vicinity of chemicals. | | | | |

METHOXYCHLOR

CAS: 72-43-5

**IDENTIFICATION AND TYPICAL USES**

Pure methoxychlor is a white, sand-like material with a slight, fruit-like odor. Technical methoxychlor is a pale buff or gray flaky powder with a fruit-like odor. It is used as an insecticide and is effective against mosquito larvae and house flies. It is also used in dairy barns to control pests to livestock and to control insects for fruits, vegetables, and forage crops. Because it is less persistent in the environment and generally less toxic than DDT, but structurally similar, it has replaced DDT in many applications.

RISK ASSESSMENT: HEALTH**General Assessment**

Methoxychlor is moderately toxic to humans by *ingestion*, *inhalation*, and skin *absorption*. It is a questionable human carcinogen with experimental carcinogenic data reported. Human data are limited and inconclusive with regard to overall toxicity. Animal studies have shown some mutation effects. There is some evidence in the references that indicates methoxychlor is a suspected animal carcinogen with long-term effects primarily in the liver.

Methoxychlor has been shown to be a central nervous system stimulant in animal studies. Symptoms of exposure by all routes include nausea, vomiting, abdominal pain, irritation, confusion, apprehension, excitability, paresthesia, dizziness, headache, disorientation, tremor, ataxia (loss of muscle coordination), stupor, coma, convulsions, respiratory collapse, and possibly death.

Skin contact will result in moderate to severe irritation with rash or burning sensation. Eye contact may also result in irritation. Caution is warranted when both inhalation and skin contact exposures are possible. Even though air levels may be within limits, personnel may be overexposed if methoxychlor should

contact the skin. The dangerous chronic dose in humans is unknown. May cause liver damage (fatty degeneration), characteristic of chronic alcoholism.

☠ Acute Health Effects

The following acute (short-term) health effects may occur immediately or shortly after exposure to methoxychlor:

- Skin:** Liquid can pass through unbroken skin. Contact may cause irritation and rash. Symptoms of exposure include headache, nausea, abdominal pain, and vomiting.
- Eye:** Severe irritation and possible damage on contact.
- Lung:** Irritation of the nose and throat. Breathing vapors can cause cough, convulsions, unconsciousness, and death.
- CNS:** A central nervous system stimulant. Symptoms include ataxia, excitement, tremors, convulsions, confusion, delirium, and irritability.

☘ Chronic Health Effects

The following chronic (long-term) health effects may occur at some time after exposure to methoxychlor and can last for months or even years:

Cancer Hazards: Methoxychlor may be a carcinogen in humans since it has been shown to cause cancer in animals. There is no evidence in the references to confirm the human carcinogenicity of methoxychlor. More research is required in this area.

Reproductive Hazard: According to information presented in the references, exposure to methoxychlor may adversely affect reproduction.

Other Chronic Effects: Long-term exposure to methoxychlor may damage the liver, kidneys, repro-

ductive system, lungs, prostate, ovaries, and may cause tumors. These effects have been documented in animals. There is no evidence of such effects in humans.

🕒 **Recommended Risk-Reduction Measures**

While methoxychlor is considered to be of relatively low toxicity in comparison to the structurally similar pesticide DDT, personnel should still avoid direct contact with this compound. If a less toxic material or compound cannot be substituted for methoxychlor, then *engineering controls* are the most effective method of reducing exposures. The best protection is to enclose operations and/or provide local exhaust ventilation at the site of methoxychlor dust release. This may be practical in manufacturing operations, but is not feasible in application since it is primarily used outdoors. While not always operationally possible, isolating operations involving methoxychlor manufacturing can also reduce exposure. Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around methoxychlor. At exposures that exceed the PEL of 15 mg/m³ (TWA), use an MSHA/NIOSH-approved chemical cartridge respirator equipped with an organic vapor filter and a dust/mist pre-filter. While a high-efficiency particulate air (HEPA) filter may not be entirely necessary for this compound, its use would certainly provide near optimum protection. The best protection is provided using a supplied-air respirator or a self-contained breathing apparatus (SCBA) with full facepiece operated in pressure demand or other positive pressure mode. If a full facepiece is not available, then chemical goggles should be worn to protect the eyes. A face shield and protective apron should also be worn. To prevent hand and skin exposures, impervious gloves should be used. Polycarbonate or butyl rubber appear to provide the best protection. However, since it will attack some rubbers and plastic materials, glove manufacturers should be contacted and permeation studies obtained *before* final glove selections have been made.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with methoxychlor.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where methoxychlor is used or stored.

There are no specific medical testing protocols established or recommended for this compound. However, if symptoms develop or overexposure is suspected, medical attention is highly recommended. Any evaluation should include a careful history of past and present symptoms with an examination. Medical tests that simply look for existing damage are not a substitute for controlling exposures.

Other methods to reduce exposure include:

- ☑ Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not used, respiratory protection should be mandatory.
- ☑ Always ensure that proper protective clothing is worn when using chemical substances.
- ☑ Wash thoroughly immediately after exposure to methoxychlor and at the end of the work shift or before eating, drinking, or smoking.
- ☑ Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of methoxychlor should be communicated to all exposed workers.
- ☑ Eye wash stations should be provided in the immediate work area for emergency use. If there is a possibility of skin exposure, then emergency shower facilities should also be provided.
- ☑ Workers whose clothing has been contaminated by methoxychlor should change into clean clothes before leaving work. Contaminated work clothing should be laundered only by individuals who have been informed of the hazards of methoxychlor.
- ☑ Specific engineering controls are recommended by NIOSH. Refer to NIOSH Criteria Document: Occupational Exposure During the Manufacture and Formulation of Pesticides (Publication Number 78-174)

RISK ASSESSMENT: ENVIRONMENT

General Assessment

Because of its use as an insecticide, methoxychlor may be present in the environment at any given time and at a variety of levels. The environment is also at risk of exposure during transportation, storage, disposal, or destruction of methoxychlor. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance. Accidental spills, large or small, where

methoxychlor contacts incompatible commodities can result in violent and even explosive reactions (depending upon conditions of spill), and possible contamination of the surrounding environmental mediums (water, soil, and air).

Methoxychlor is considered a non-combustible solid. However, it may be present (dissolved) in some flammable liquids such as benzene. Also, because it is incompatible with many strong oxidizers, common alkaline materials, and some metals, such as iron and aluminum, extreme caution is required in handling, storage, transportation, and disposal of methoxychlor. It will also attack some forms of rubber and plastic. These characteristics also require special consideration during any emergency situation involving a leak or spill of methoxychlor powder or dust.

Methoxychlor is a chlorinated hydrocarbon insecticide used to control a variety of pests. It has served as a replacement for DDT in most cases. Methoxychlor enters the environment in agricultural runoff, industrial discharges, and spills.

☠ *Acute Ecological Effects*

Acute (short-term) toxic effects may include the death of animals, birds, or fish and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to methoxychlor.

Methoxychlor has high acute toxicity to aquatic life. Methoxychlor has caused injuries to agricultural crops and tree species. Insufficient data are available to evaluate or predict on the short-term effects of methoxychlor to birds and land animals.

☞ *Chronic Ecological Effects*

Chronic (long-term) toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals.

Methoxychlor has high chronic toxicity to aquatic life. Insufficient data are available to evaluate or predict the long-term effects of methoxychlor to plants, birds, or land animals.

💧 *Water Solubility*

Methoxychlor is only very slightly soluble in water. Concentrations of less than 1 milligram will mix with a liter of water.

⌚ *Persistence in the Environment*

Methoxychlor is moderately persistent in the water, with a half-life of 20 to 200 days. The half-life of a

pollutant is the amount of time it takes for one-half of the chemical to be degraded. About 50% of methoxychlor will eventually end up in terrestrial soil; approximately 46.8% will end up in aquatic sediments; about 3% in water; and the remainder will end up in the suspended aquatic solids.

🐟 *Bioaccumulation in Aquatic Organisms*

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans.

The concentration of methoxychlor found in fish tissues is expected to be much higher than the average concentration of methoxychlor in the water from which the fish was taken.

🛡️ *Recommended Risk-Reduction Measures*

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in a leak or spill of methoxychlor into the environment. The correct use of DOT labeling (per the MSDS) on all containers, trucks, and rail cars will enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of methoxychlor should be segregated from incompatible materials to minimize the risk of cross-contamination or contact. Buildings or storage areas should be equipped with appropriate fire protection systems (alarms, sprinklers). Proper ventilation and protective equipment should be used while handling the powders or while preparing aqueous solutions.

If a spill or leak to the environment has occurred, fire department, emergency response and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those trained in proper spill containment procedures. If methoxychlor should contact the water table, aquifer, or navigable waterway, reclamation procedures should be initiated as soon as practical. It is only very slightly soluble in water and partial or even total remediation may be possible. The local and/or state emergency response authorities must be notified. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of methoxychlor. If methoxychlor is

spilled or leaked, the following specific steps are recommended:

- ☑ Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened for normal work.
- ☑ Ventilate area of spill or leak.
- ☑ Collect powdered materials using a vacuum equipped with a HEPA filter. Do NOT dry sweep. Damp mop residues. Absorb solution spills in vermiculite or other material and place in sealed drum for disposal or reclamation.
- ☑ It may be necessary to dispose of methoxychlor as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving methoxychlor can present a significant threat to business operations. The loss or damage of equipment or facilities can significantly affect fiscal viability. Lawsuits that may result from personnel injury/death, public exposures, and/or environmental contamination will also require a serious expenditure of resources. Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business. Always remember that anytime terms “cancer” or “carcinogen” are used, public emotion, hysteria, and ignorance can run equally high. This must be carefully considered whenever developing or implementing public relations policies.

Recommended Risk-Reduction Measures

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures for responding to chemical incidents. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

Dry chemical, alcohol-resistant foam, carbon dioxide, water spray, or fog.

Special Fire Fighting Procedures

Poisonous gases are produced in fire. Wear full protective clothing and self-contained breathing apparatus (SCBA). Use blanketing effect with foam to smother large fires. Continue to cool containers with water after fire is extinguished. Water on fire itself may be ineffective and actually spread fire further.

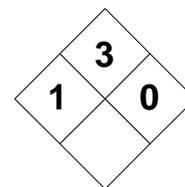

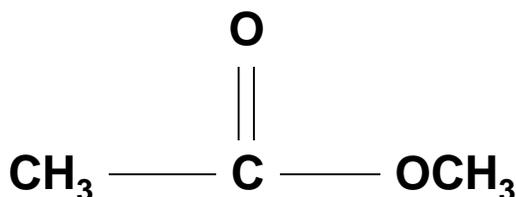

Unusual Fire and Explosion Hazards

Immediately withdraw if rising sound from venting device is heard or if fire is causing discoloration to the tank. Evacuate 1500 feet radius if fire becomes uncontrollable or container is exposed to direct flame. Vapors are heavier than air and may travel a distances to ignition source to flashback.

| SECTION V - REACTIVITY DATA | | | | |
|---|----------------------------|--|--|---|
| Stability | | Conditions to Avoid Methyl acetate is stable under normal conditions of storage and operation. Avoid contact with incompatible materials. Keep away from heat, flame, and other sources of ignition. | | |
| Stable X | Unstable | Incompatibility (<i>materials to avoid</i>) Reacts violently in contact with nitrates, strong oxidizers, alkalis, and acids. Reacts slowly with water to form acetic acid and methanol. | | |
| Hazardous Polymerization | | Conditions to Avoid Under normal conditions of temperature and pressure, hazardous polymerization of methyl acetate is not expected to occur. | | |
| May Occur | Will Not Occur X | Hazardous Decomposition or By-products When heated to decomposition, methyl acetate emits toxic oxides of carbon (dioxide and monoxide) and acrid and irritating fumes. | | |

| Primary Route(s) of Entry: | | Inhalation? X | Absorption (skin)? | Ingestion? X |
| Health Hazards INHALATION: Irritation of the eyes, nose, throat, and respiratory tract with a possibility for narcosis and headache. Systemic effects include olfactory changes, conjunctiva inflammation, chest tightness, nervous irritation, dizziness, drowsiness, dyspnea, palpitation, and corneal edema. SKIN & EYES: Will irritate the skin. May cause contact dermatitis. Eye contact may cause corneal damage with cloudy swelling, and fatty degeneration of the viscera. INGESTION: May cause headache, drowsiness, and unconsciousness. | | | | |
| Carcinogenicity Unknown Human Unknown Animal | NTP Listed? No | IARC Cancer Review Group? No | OSHA Regulated? 29 CFR 1910.1000 Table Z-1 | Target Organs? Respiratory system, skin, eyes, CNS. |
| Medical Conditions Generally Aggravated by Exposure None reported. | | | | |
| Emergency and First-aid Procedures Eye contact: Flush immediately with water for 15 minutes (minimum); seek medical attention. Skin contact: Remove all contaminated clothing. Immediately wash area with large amounts of soap and water. Seek medical assistance. For inhalation: Remove the person from exposure. Provide respiratory assistance and CPR. Transfer to medical facility. If swallowed: Seek medical attention immediately. Call poison control center for advice. Give 1-2 glasses of milk or water to dilute. Do NOT induce vomiting unless advised otherwise. Never give an unconscious or convulsing person anything by mouth. | | | | |
| SECTION VII - PRECAUTIONS FOR SAFE HANDLING AND USE | | | | |
| Steps to be Taken in Case Material is Released or Spilled Contain spills using absorbent material (vermiculite or other). Ventilate area of spill. Remove all ignition sources. Have water source available in case of fire. Store materials in DOT-approved containers. Restrict those not involved in cleanup from entering area. Notify appropriate authorities, as required. | | | | |
| Preferred Waste Disposal Method Incineration in chemical incinerator equipped with scrubber and afterburner. | | | | |
| Precautions to be Taken in Handling and Storage Store in tightly closed containers in a cool, dark, well-ventilated area. Protect containers from physical damage. Keep heat, fire, and flame away. If possible, automatically transfer liquids between containers. | | | | |
| Other Precautions and Warnings Bulk storage of methyl acetate is not recommended. Ground and bond all metal containers. | | | | |
| SECTION VIII - CONTROL MEASURES AND PERSONAL PROTECTIVE EQUIPMENT | | | | |
| Respiratory Protection (<i>specify type</i>) Where potential exists for exposure over 400 ppm, use an MSHA/NIOSH-approved full facepiece respirator with an organic vapor cartridge. For high exposures, use a self-contained breathing apparatus (SCBA) with full facepiece operated in pressure demand or other positive pressure mode. | | | | |
| Ventilation Local exhaust or general mechanical systems recommended. | | | | |
| Protective Gloves Butyl Rubber or Neoprene | | Eye Protection Chemical Goggles or Face Mask | | Other Protective Clothing Impermeable Apron |
| Work/Hygiene Practices Always wash hands thoroughly after using chemical; never bring food, drink, or smoking materials into vicinity of chemicals. | | | | |

METHYL ACETATE

CAS: 79-20-9

**IDENTIFICATION AND TYPICAL USES**

Methyl acetate is a colorless liquid with a characteristic, fruity, ether-like odor. It is used as a solvent for lacquers, resins, oils, and nitrocellulose. It is also used in paint removers, as a flavoring agent, in agriculture, and in the manufacture of artificial leather.

RISK ASSESSMENT: HEALTH***General Assessment***

Methyl acetate is a human systemic irritant by *inhalation* and may cause toxic systemic effects. It is mildly toxic by *ingestion*. Skin contact can produce localized effects but dermal absorption has not been reported. While its specific carcinogenic and teratogenic properties are unknown, mutation data have been reported.

Inhalation of methyl acetate vapors is not likely to occur under normal operating conditions. The extremely irritating properties of the vapor will cause personnel to vacate the area before toxic exposure levels occur. However, should an exposure occur by inhalation, it will likely result in irritation of the eyes, nose, throat, and upper respiratory tract, including the mucosa (particularly the eyes, gums, and respiratory passages). Inhalation can cause changes in the sense of smell (olfactory changes), conjunctiva irritation, and pulmonary changes. In high concentrations, there can be additional pulmonary effects and/or depression of the central nervous system with mild narcotic effects including dizziness, drowsiness, tightness in chest, palpitation, dyspnea, conjunctivitis, and corneal edema.

Skin contact results in the mild irritation and, if allowed to remain in contact with the liquid for prolonged periods, removal of the skin's natural protective oily layer on its surface with subsequent drying, cracking, and possible secondary infections and dermatitis. Eye contact can cause serious damage to the

cornea with a possibility for permanent effects to vision.

Ingestion of methyl acetate may cause headache, drowsiness, unconsciousness, and unspecified gastrointestinal effects.

☠ *Acute Health Effects*

The following acute (short-term) health effects may occur immediately or shortly after exposure to methyl acetate:

Skin: Mild to moderate irritation. Will remove the skin's protective oily layer to cause drying, cracking, and possible secondary infection.

Eye: Severe irritation which can lead to injury and permanent damage if allowed to remain in contact with the eyes.

Lung: Irritation of the eyes, nose, throat and lungs (especially the mucus membranes). May cause changes in the sense of smell and in pulmonary function.

CNS: High concentrations can depress the central nervous system leading to narcoses and possible loss of consciousness.

☘ *Chronic Health Effects*

The following chronic (long-term) health effects may occur at some time after exposure to methyl acetate and can last for months or even years:

Cancer Hazards: According to the references, methyl acetate has not been adequately tested for its ability to cause cancer in test animals. However, mutation data have been reported. This does not mean that methyl acetate is carcinogenic. It does mean that further research is required and caution is warranted.

Reproduction: According to the references, methyl acetate has not been adequately tested for its ability to adversely affect reproduction in test animals.

Other Chronic Effects: Very high or prolonged exposure may lead to chronic skin irritation and possible dermatitis.

Recommended Risk-Reduction Measures

Personnel should avoid direct contact with methyl acetate. The best risk reduction measure is to use a less toxic chemical as a substitute for methyl acetate. If this is not possible or feasible, then *engineering controls* are the most effective method of reducing exposures. The best protection is to enclose operations and/or provide local exhaust ventilation at the site of chemical release. While not always operationally feasible, isolating operations can also reduce exposure risk.

Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around methyl acetate. For exposures over 200 ppm (8 hours), an MSHA/NIOSH-approved chemical respirator with an organic vapor cartridge should be used. For higher exposures, or when the exposure level is unknown (as in an emergency), a self-contained breathing apparatus (SCBA) with full facepiece and operated in pressure demand mode or a supplied-air respirator with full facepiece operated in pressure demand are the recommended respiratory protection methods of choice. If a full facepiece is not available, then chemical goggles should be worn to protect the eyes. Whenever a chemical splash hazard exists, a face shield and a protective apron should be worn. To prevent hand and skin exposures, impervious gloves should be used. Neoprene, butyl rubber, or chlorinated polyethylene products should provide adequate protection. However, glove manufacturers should be contacted to obtain permeation studies *before* gloves are selected.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with methyl acetate.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where methyl acetate is used or stored.

If symptoms develop or overexposure is suspected, the following medical tests are recommended:

- ☑ Liver and kidney function tests.
- ☑ Lung function tests.
- ☑ Skin testing with dilute methyl acetate to help diagnose allergy (performed by a qualified allergist).
- ☑ Methyl acetate is hydrolyzed to methanol in the body. Monitoring serum methanol and urine methanol levels may be useful in determining exposure.

Any medical evaluation should include a careful history of past and present symptoms with an examination. Medical tests that look for existing damage are not a substitute for controlling exposures.

Other methods to reduce exposure include:

- ☑ Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not used, respiratory protection should be mandatory.
- ☑ Always ensure that proper protective clothing is worn when using chemical substances and that personnel are trained in its use and care.
- ☑ Wash thoroughly immediately after exposure to methyl acetate and at the end of the work shift or before eating, drinking, or smoking.
- ☑ Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of methyl acetate should be communicated to all exposed and potentially exposed workers.
- ☑ Never eat, drink, or smoke in areas where methyl acetate is used, handled, or stored.

RISK ASSESSMENT: ENVIRONMENT

General Assessment

The environment is at risk of exposure during transportation, storage, disposal, or destruction of methyl acetate. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance.

Accidental spills, large or small, can result in fire, explosion, and possible contamination of the surrounding environmental mediums (water, soil, and air). Methyl acetate is considered a Class IB flammable liquid (according to OSHA 29 CFR 1910.106). Its low flash point and relatively low boiling point present a serious fire and explosion hazard concern. Also, because it is incompatible with a number of common materials, especially strong oxidizers and acids, con-

tact can result in violent and explosive reactions. It can also form explosive mixtures in air and can ignite on contact with heat, fire, or sparks. These characteristics require special consideration during any emergency situation involving a leak or spill of methyl acetate.

The proper disposal/destruction method for methyl acetate is to burn it in a chemical incinerator equipped with an afterburner and air scrubber. Methyl acetate can enter the environment through unchecked industrial discharges into effluents and through spills.

☠ *Acute Ecological Effects*

Acute (short-term) toxic effects may include the death of animals, birds, or fish, and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to methyl acetate. This chemical has moderate acute toxicity to aquatic life. Insufficient data are available to evaluate or predict the short-term effects of methyl acetate to plants, birds, or terrestrial animals.

🕒 *Chronic Ecological Effects*

Chronic toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals. Methyl acetate has moderate chronic toxicity to aquatic life. Insufficient data are available to evaluate or predict the long-term effects of methyl acetate to plants, birds, or land animals.

💧 *Water Solubility*

Methyl acetate is moderately soluble in water. Concentrations of 1 to 1000 milligrams will mix with a liter of water.

🕒 *Persistence in the Environment*

Methyl acetate is slightly persistent in water, with a half-life of between 2 to 20 days. The half-life of a pollutant is the amount of time it takes for one-half of the chemical to be degraded.

🐟 *Bioaccumulation in Aquatic Organisms*

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans.

The concentration of methyl acetate found in fish tissues is expected to be somewhat higher than the average concentration of methyl acetate in water from which the fish was taken.

🛡️ *Recommended Risk-Reduction Measures*

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in a leak or spill to the environment. The correct use of DOT labeling (per the MSDS) on all containers, trucks, and rail cars will enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of methyl acetate should be segregated from incompatible chemicals to minimize the risk of cross-contamination or contact. Buildings designated for storage should be equipped with appropriate fire protection systems (alarms, sprinklers, emergency lighting, portable extinguishers).

If a spill or leak to the environment has occurred, fire department, emergency response, and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those trained in proper spill containment procedures using non-sparking tools. Contaminated soils should be removed for incineration and replaced with clean soil.

If methyl acetate should contact the water table, aquifer, or navigable waterway, time is of the essence. It is moderately soluble in water and, therefore, total containment and remediation may not be possible. When such spills occur, the local and/or state emergency response authorities must be notified. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of methyl acetate. If methyl acetate is spilled or leaked, the following specific steps are recommended:

- Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened for normal work.
- Ventilate area of spill or leak.
- Remove all ignition sources from area immediately.
- Absorb liquids in vermiculite, dry sand, earth, or a similar material and deposit in sealed containers. Use non-sparking tools. Keep water away if possible since methyl acetate will slowly react to form acetic acid and methanol in contact with water.

- ☑ It may be necessary to dispose of methyl acetate as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving methyl acetate can present a moderate threat to business operations. The loss or damage of equipment or facilities can significantly affect fiscal viability. Lawsuits that may result from personnel injury/death, public exposures, and/or environmental contamination will also require a serious expenditure of resources.

Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business.

Recommended Risk-Reduction Measures

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures or policies intended to manage the use of chemicals in the workplace. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

METHYL ACRYLATE

CAS: 96-33-3

**IDENTIFICATION AND TYPICAL USES**

Methyl acrylate is a colorless liquid with an acrid odor. It is used as a monomer in the manufacture of leather finish resins, textile and paper coatings, and plastic films. It is also a resin in the purification and decolorization of industrial effluents or an aid in timed release and disintegration of pesticides, for the polymerization of radioactive wastes, and in the preparation of acrylic polymers.

RISK ASSESSMENT: HEALTH**General Assessment**

Methyl acrylate is a toxic poison to humans by *inhalation*, *ingestion*, and by skin contact (*absorption*). It is a questioned animal carcinogen, but there is insufficient data regarding its carcinogenicity in humans. Prolonged exposures may lead to congestion of the lungs and changes in the heart, kidney, and liver.

Inhalation results in irritation of the mucus membranes of the eyes, nose, throat, and respiratory system. It can cause changes in the sense of smell and in pulmonary function. In addition, there may be symptoms such as lethargy, coughing, wheezing, fatigue, cyanosis, and convulsive movements. High concentrations can cause dizziness with dyspnea, nausea, headache, vomiting, and can lead to death as a result of chemical pneumonitis or pulmonary edema (fluid in the lungs). Symptoms of pulmonary edema can be delayed up to 48 hours following exposure which may create a false sense of security with regard to health exposure risk.

Skin contact can cause serious localized irritation at the site of contact with marked erythema, blisters and edema, itching, and inflammation. There may be first degree burns on short exposures and second degree burns on prolonged exposures. Repeated exposures may cause sensitivity and dermatitis.

Ingestion of methyl acrylate causes irritation of the gastrointestinal tract with irritation of the mouth, lips, throat, painful swallowing, abdominal cramps, nausea, vomiting, diarrhea, shock, and possible loss of consciousness. Subsequent absorption through the digestive process can lead to toxic systemic effects, especially changes to liver, lung, and kidney tissues.

☠ Acute Health Effects

The following acute (short-term) health effects may occur immediately or shortly after exposure to methyl acrylate:

Skin: Serious irritation and possible first or second degree burns. There can be marked localized irritation, erythema, edema, and sensitization.

Eye: Severe irritation which can lead to injury, burns, painful irritation, and permanent damage if allowed to remain in contact.

Lung: Irritation of the eyes, nose, throat and lungs (especially the mucus membranes). May cause changes in the sense of smell and in pulmonary function. Can lead to chemical pneumonitis and/or pulmonary edema (fluid in the lungs).

CNS: High concentrations may cause dizziness, headache, nausea, vomiting, dyspnea, lethargy, and convulsive movements.

☘ Chronic Health Effects

The following chronic (long-term) health effects may occur at some time after exposure to methyl acrylate and can last for months or even years:

Cancer Hazards: According to the references, methyl acrylate has been investigated for its ability to cause cancer in test animals and there is insufficient evidence to determine its carcinogenic effects. Its car-

Risk Management for Hazardous Chemicals

cinogenicity is considered questioned. Mutation data have been reported and many scientists believe that such chemicals may pose a cancer risk

Reproduction: According to the references, methyl acrylate has not been adequately tested for its ability to adversely affect reproduction in test animals.

Other Chronic Effects: Very high or prolonged exposure may lead to congestion of the lungs and possible changes in the liver or kidneys.

Recommended Risk-Reduction Measures

Because of its unknown but questioned carcinogenicity, as well as its known ability to cause serious topical and systemic effects, personnel should avoid direct contact with methyl acrylate. The best risk reduction measure is to use a less toxic chemical as a substitute for methyl acrylate. If this is not possible or feasible, then *engineering controls* are the most effective method of reducing exposures. The best protection is to enclose operations and/or provide local exhaust ventilation at the site of chemical release. While not always operationally feasible, isolating operations can also reduce exposure risk.

Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around methyl acrylate. For exposures exceeding the 10 ppm PEL (8-hour TWA), a supplied-air respirator with full facepiece operated in positive pressure mode, or a self-contained breathing apparatus (SCBA) with full facepiece and operated in pressure demand mode are the recommended respiratory protection methods of choice. If a full facepiece is not available, then chemical goggles should be worn to protect the eyes. Whenever a chemical splash hazard exists, a face shield and a protective apron should be worn. To prevent hand and skin exposures, impervious gloves should be used. Glove manufacturers should be contacted to obtain permeation studies before gloves are selected.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with methyl acrylate.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where methyl acrylate is used or stored.

Before beginning employment and at regular intervals thereafter (e.g., annually), those persons having

frequent or potentially high exposures should be given the following medical tests:

Lung function tests.

If symptoms develop or overexposure is suspected, the following medical tests are recommended:

Liver and kidney function tests.

Lung function tests.

Skin testing with dilute methyl acrylate to help diagnose allergy (performed by a qualified allergist).

Consider chest X-ray following acute overexposure (may be negative if taken immediately after exposure due to delayed onset of pulmonary edema).

Any medical evaluation should include a careful history of past and present symptoms with an examination. Medical tests that look for existing damage are not a substitute for controlling exposures. Also, since smoking can cause heart disease, emphysema, and other respiratory disorders, smokers exposed to methyl acrylate may develop symptoms much quicker and with greater intensity than non-smokers under identical exposure conditions. Prudent risk management requires careful consideration of *all* possible factors which may be causing the appearance of exposure symptoms.

Other methods to reduce exposure include:

Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not used, respiratory protection should be mandatory.

Always ensure that proper protective clothing is worn when using chemical substances.

Wash thoroughly immediately after exposure to methyl acrylate and at the end of the work shift or before eating, drinking, or smoking.

Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of methyl acrylate should be communicated to all exposed workers.

Never eat, drink, or smoke in areas where methyl acrylate is used, handled or stored.

Work clothing contaminated with methyl acrylate should never be worn home where family members can be exposed. It should be laundered only

by those who have been trained on the health risks associated with methyl acrylate.

RISK ASSESSMENT: ENVIRONMENT

General Assessment

The environment is at risk of exposure during transportation, storage, disposal, or destruction of methyl acrylate. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance. Accidental spills, large or small, can result in fire, explosion, and possible contamination of the surrounding environmental mediums (water, soil, and air).

Methyl acrylate is considered a Class IB flammable liquid (according to OSHA 29 CFR 1910.106). Its low flash point and relatively low boiling point present a serious fire and explosion hazard concern. Also, because it is incompatible with a number of common materials, especially strong oxidizers, contact can result in violent and explosive reactions. It can also form explosive mixtures in air and can ignite on contact with heat, fire, or sparks. Heat can cause methyl acrylate to react by itself. If this happens in a closed container, an explosion can occur. Methyl acrylate usually contains an inhibitor such as hydroquinone or its methyl ether to prevent a self-reaction. If the inhibitor is absent or present in too low a quantity, the explosive reaction may occur without the application of heat. These characteristics require special consideration during any emergency situation involving a leak or spill of methyl acrylate.

Methyl acrylate can enter the environment through unchecked industrial discharges and through spills.

☠ Acute Ecological Effects

Acute (short-term) toxic effects may include the death of animals, birds, or fish, and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to methyl acrylate. This chemical has moderate acute toxicity to aquatic life. Insufficient data are available to evaluate or predict the short-term effects of methyl acrylate to plants, birds, or terrestrial animals.

☞ Chronic Ecological Effects

Chronic toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals. Methyl acrylate has moderate chronic

toxicity to aquatic life. Insufficient data are available to evaluate or predict the long-term effects of methyl acrylate to plants, birds, or land animals.

💧 Water Solubility

Methyl acrylate is moderately soluble in water. Concentrations of 1 to 1000 milligrams will mix with a liter of water.

🕒 Persistence in the Environment

Methyl acrylate is slightly persistent in water, with a half-life of between 2 to 20 days. The half-life of a pollutant is the amount of time it takes for one-half of the chemical to be degraded. About 85% of methyl acrylate will eventually end up in the air; the remainder will end up in water.

🐟 Bioaccumulation in Aquatic Organisms

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans.

The concentration of methyl acrylate found in fish tissues is expected to be about the same as the average concentration of methyl acrylate in water from which the fish was taken.

🛡 Recommended Risk-Reduction Measures

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in a leak or spill to the environment. The correct use of DOT labeling (per the MSDS) on all containers, trucks, and rail cars will enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of methyl acrylate should be segregated from incompatible chemicals to minimize the risk of cross-contamination or contact. Buildings designated for storage should be equipped with appropriate fire protection systems (alarms, sprinklers, emergency lighting, portable extinguishers). Equipment should be designed to meet explosion-proof standards.

If a spill or leak to the environment has occurred, fire department, emergency response, and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those trained in proper spill containment procedures using non-sparking tools. Contaminated soils should be removed for incineration and replaced with clean soil.

Risk Management for Hazardous Chemicals

If methyl acrylate should contact the water table, aquifer, or navigable waterway, time is of the essence. It is moderately soluble in water and, therefore, containment and remediation may not be entirely possible. When such spills occur, the local and/or state emergency response authorities must be notified. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of methyl acrylate.

If methyl acrylate is spilled or leaked, the following specific steps are recommended:

- ☑ Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened for normal work.
- ☑ Ventilate area of spill or leak.
- ☑ Remove all ignition sources.
- ☑ Absorb liquids in vermiculite, dry sand, earth, or a similar material and deposit in sealed containers. Use non-sparking tools.
- ☑ It may be necessary to dispose of methyl acrylate as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving methyl acrylate can present a moderate threat to business operations. The loss or damage of equipment or facilities can significantly affect fiscal viability. Lawsuits that may result from personnel injury/death, public exposures, and/or environmental contamination will also require a serious expenditure of resources.

Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business. Always remember that anytime the terms “cancer” or “carcinogen” are used, public emotion, hysteria, and ignorance can run equally high. This should be carefully considered when developing or implementing a public relations policy.

☉ Recommended Risk-Reduction Measures

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures or policies intended to manage the use of chemicals in the workplace. A company official should be pre-designated as

a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

|----------|----------|----------|-------|---|---|---|
| 2 | 3 | 2 | | 0 = Minimum Hazard 1 = Slight Hazard 2 = Moderate Hazard 3 = Serious Hazard 4 = Severe Hazard | HEALTH = BLUE FIRE = RED REACTIVITY = YELLOW OTHER = WHITE | OX = Oxidizer ACID = Acid ALK = Alkali COR = Corrosive W = Use No Water |

SECTION I - GENERAL INFORMATION

| | | |
|---|---|---------------------------------|
| Characterization Organic Cyanides (Nitriles) | RCRA Number U152 | EPA Class Toxic Waste |
| DOT Proper Shipping Name Flammable Liquid, Poisonous, N.O.S. | Chemical Abstract Service (CAS) Number 126-98-7 | |
| DOT Hazard Class and Label Requirements Flammable Liquid and Poison | DOT Emergency Guide Code 28 (Inhibited) | |
| DOT Identification Number UN 1992 | Chemical Formula CH₂:C(CH₃)CN | |

Synonyms

2-Cyanopropene-1, isoprene cyanide; methacrylonitrile; α -methylacrylonitrile; 2-methylpropenenitrile.

SECTION II - HAZARDOUS INGREDIENTS AND IDENTITY INFORMATION

| Hazardous Components (specific identity) | OSHA Exposure Criteria | NIOSH Exposure Criteria | Immediately Dangerous to Life and Health (IDLH) | ACGIH Exposure Criteria |
|---|---|---|---|---|
| Methylacrylonitrile (derived: By vapor-phase catalytic oxidation of methy-lamine). 1 ppm = 2.79 mg/m³ | PEL: Not Established STEL: Not Established | REL (skin): 1 ppm 3 mg/m³ STEL: Not Established | Not Determined | TLV (skin): 1 ppm 3 mg/m³ STEL: Not Established |

SECTION III - PHYSICAL AND CHEMICAL CHARACTERISTICS

| | |
|--|--|
| Boiling Point 194°F (90°C) | Specific Gravity (H ₂ O = 1) 0.80 |
| Vapor Pressure (mm Hg) 71 at 77°F (25°C) | Molecular Weight 67.1 |
| Vapor Density (Air = 1) Not Found | Freezing Point -32°F (-36°C) |

Solubility

Partially soluble (37%) in water. Soluble in acetone, thermoplastic, resistant to acids and alkalis.

Appearance and Odor

Clear, colorless liquid with an odor of bitter almonds.

SECTION IV - FIRE AND EXPLOSION HAZARD DATA

| | |
|---|--|
| Flash Point (method used) 34°F (1°C) closed cup | Explosive Limits in Air % by Volume LEL: 2% UEL: 6.8% |
| NFPA Classification Class 1B Flammable Liquid | Autoignition Temperature Not Found |

Extinguishing Media

Carbon dioxide, dry chemical, alcohol foam. Water may be ineffective.

Special Fire Fighting Procedures

Poisonous gases are produced in fire. Wear full protective clothing and self-contained breathing apparatus (SCBA). Keep fire-exposed containers cool with water spray. Do not release runoff from fire fighting efforts to sewers or waterways. Contain and collect for disposal.

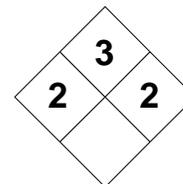

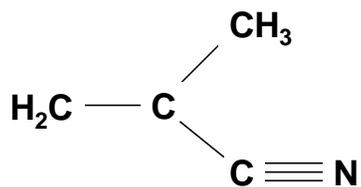

Unusual Fire and Explosion Hazards

Dilute solutions are also flammable. Vapors form explosive mixtures in air. Heat will build pressure and may rupture closed storage containers. Vapors are heavier than air; they may travel a distance to cause fire or explosion due to flashback phenomenon. Heat of fire may cause violent polymerization to occur.

| SECTION V - REACTIVITY DATA | | | | |
|---|--------------------------|--|--------------------------------|---|
| Stability | | Conditions to Avoid Normally stable under routine conditions. Dangerous fire hazard when exposed to heat and flame. Avoid contact with incompatible materials. | | |
| Stable | Unstable X | Incompatibility (<i>materials to avoid</i>) Incompatible with strong oxidizers (chlorine, fluorine, bromine), strong bases, strong acids, and strong reducing agents. | | |
| Hazardous Polymerization | | Conditions to Avoid Under normal conditions of temperature and pressure, hazardous polymerization of methylacrylonitrile MAY occur. Violent polymerization occurs in the presence of caustic alkalis and at elevated temperatures. | | |
| May Occur X | Will Not Occur | Hazardous Decomposition or By-products Polymerizes violently in presence of concentrated alkali or at elevated temperature. It undergoes photochemical polymerization, liberating heat. Violent rupture of glass containers can occur. | | |
| SECTION VI - HEALTH HAZARD DATA | | | | |
| Primary Route(s) of Entry: | | Inhalation? X | Absorption (skin)? X | Ingestion? X |
| Health Hazards | | | | |
| INHALATION: Asphyxia, headache, chest pains, dyspnea, lightheadedness, coughing, weakness, and fatigue. High concentrations can cause lachrymation, somnolence (sleepiness), jaundice, diarrhea, nausea, vomiting, and death. Extremely irritating to the eyes, nose, throat, and mucosa of the respiratory tract. | | | | |
| ABSORPTION: Headache, lightheadedness, sneezing, weakness, nausea, and vomiting. Severe intact-action can result in loss of consciousness, convulsions, respiratory arrest, and death. Methylacrylonitrile is a skin irritant. It may cause blistering after a few hours. | | | | |
| INGESTION: Gastrointestinal irritation and inflammation of the digestive tract. | | | | |
| Carcinogenicity Unknown Human Unknown Animal | NTP Listed? No | IARC Cancer Review Group? No | OSHA Regulated? No | Target Organs? Respiratory system; skin; eyes; CNS. |
| Medical Conditions Generally Aggravated by Exposure Respiratory impairments, (asthma; skin conditions (dermatitis); and cardiovascular disorders. | | | | |
| Emergency and First-aid Procedures | | | | |
| Eye contact: Flush immediately with water for 15 minutes (minimum); seek medical attention. Skin contact: Remove all contaminated clothing. Immediately wash area with large amounts of soap and water. Seek medical assistance. For inhalation: Remove the person from exposure. Provide respiratory assistance and CPR. Transfer to medical facility. If swallowed: Seek medical attention immediately. Give 1 or 2 glasses of water or milk. Do NOT induce vomiting, unless told to do so by a doctor. | | | | |
| SECTION VII - PRECAUTIONS FOR SAFE HANDLING AND USE | | | | |
| Steps to be Taken in Case Material is Released or Spilled | | | | |
| Contain spills using absorbent material (vermiculite, or other). Ventilate area of spill. Have water source available in case of fire. Place materials in DOT-approved containers. Restrict those not involved in cleanup from entering area. Remove all ignition sources. | | | | |
| Preferred Waste Disposal Method | | | | |
| Chemical incinerator equipped with scrubber and afterburner. | | | | |
| Precautions to be Taken in Handling and Storage | | | | |
| Methylacrylonitrile is highly volatile. Store in tightly closed containers in a cool, dark, well-ventilated area. Keep fire and flame away. Use non-sparking tools to open or close containers. | | | | |
| Other Precautions and Warnings | | | | |
| If exposed to heat or light, uninhibited methylacrylonitrile can react violently by itself, leading to an explosion of closed containers. Ground and bond all metal containers during transfer operations. | | | | |
| SECTION VIII - CONTROL MEASURES AND PERSONAL PROTECTIVE EQUIPMENT | | | | |
| Respiratory Protection (<i>specify type</i>) | | | | |
| Exposure level is low and difficult to monitor. At any exposure level, recommend using a self-contained breathing apparatus (SCBA) with full facepiece in pressure demand or other positive pressure mode. | | | | |
| Ventilation | | | | |
| Local exhaust or general mechanical systems recommended. | | | | |
| Protective Gloves Impervious Material | | Eye Protection Chemical Goggles or Face Mask | | Other Protective Clothing Protective Apron |
| Work/Hygiene Practices | | | | |
| Always wash hands thoroughly after using chemical; never bring food, drink, or smoking materials into vicinity of chemicals. | | | | |

METHYLACRYLONITRILE

CAS: 126-98-7

**IDENTIFICATION AND TYPICAL USES**

Methylacrylonitrile is a clear, colorless liquid with an odor similar to bitter almonds. It is used in the manufacture of coatings and elastomer and as an intermediate in the preparation of acids, amines, amides, and esters. It is also used in making dyes, acrylic fibers, fertilizers, and in organic synthesis.

RISK ASSESSMENT: HEALTH**General Assessment**

Human exposure to methylacrylonitrile can occur through all routes of entry into the body: *inhalation*, *ingestion*, and dermal *absorption*. Each present a moderate level of toxicity. Methylacrylonitrile is readily absorbed through the respiratory tract, the gastrointestinal tract, and through unbroken skin. Absorption through the skin can result in toxic symptoms such as headache, lightheadedness, sneezing, weakness, nausea, and vomiting. In humans, many symptoms are non-specific but appear to be related to the central nervous system (CNS), the respiratory tract, gastrointestinal tract, and the skin.

Inhalation of this compound can cause asphyxia, headache, mild to severe chest pains, weakness, lachrymation (tearing), dyspnea (labored breath), lightheadedness, and coughing. Severe intoxication can cause jaundice, diarrhea, loss of consciousness, respiratory arrest, convulsions, and death. There is also evidence to show that methylacrylonitrile can cause congestion in all types of organs and damage to the liver, blood, or the central nervous system (CNS).

☠ Acute Health Effects

The following acute (short-term) health effects may occur immediately or shortly after exposure to methylacrylonitrile:

Skin: Severe irritation and blistering a few hours after exposure.

Eye: Burns leading to permanent damage.

Lung: Irritation causing coughing, congestion, and shortness of breath.

CNS: Inhalation of high concentrations of the vapor may cause sleepiness, dizziness, loss of consciousness, or death. Lower exposures can cause weakness, headache, confusion, nausea, vomiting, and can also lead to death.

☞ Chronic Health Effects

The following chronic (long-term) health effects may occur at some time after exposure to methylacrylonitrile and can last for months or even years:

Cancer Hazards: According to information presented in the references, methylacrylonitrile has not been adequately tested for its ability to cause cancer in test animals.

Reproductive Hazard: There is no evidence that methylacrylonitrile adversely affects reproduction.

Other Chronic Effects: None reported.

🛡 Recommended Risk-Reduction Measures

Personnel should avoid direct contact with methylacrylonitrile. Unless a less toxic chemical can be substituted for a hazardous substance, *engineering controls* are the most effective method of reducing exposures. The best protection is to enclose operations and/or provide local exhaust ventilation at the site of chemical release. While not always operationally feasible, isolating operations can also reduce exposure.

Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around methylacrylonitrile. The exposure level is extremely low (1 ppm) and difficult to accurately monitor. A self-contained breath-

ing apparatus (SCBA) with full facepiece operated in pressure demand or a supplied-air respirator operated in continuous flow mode are the recommended respiratory protection of choice. If a full facepiece is not available, then chemical goggles should be worn to protect the eyes. Whenever a chemical splash hazard exists, a face shield and a rubber apron should be worn. To prevent hand and skin exposures, gloves should be used. Glove manufacturers should be contacted and permeation studies obtained *before* final glove selections are made.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with methylacrylonitrile.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where methylacrylonitrile is used or stored.

Medical testing of personnel should be performed before the first exposure and at least annually thereafter. As per OSHA requirements, these tests must be provided by the employer and include:

- Complete physical examination.
- Stool test for blood (employees over 40).

In addition, for those with frequent or potentially high exposure (half the TLV or greater, or significant skin contact), the following are recommended before beginning work and at regular intervals thereafter:

- Urine thiocyanate levels.
- Lung function (pulmonary function) tests.

If symptoms develop or overexposure is suspected, the following additional tests may be useful:

- Blood cyanide level.
- Thyroid function test.
- Consider chest X-ray after acute overexposure.

Any evaluation should include a careful medical history of past and present symptoms with an examination. However, medical tests that evaluate existing damage are not a substitute for controlling exposure. Antidotes following exposure to cyanides include:

- Sistine and *N*-acetyl Sistine are somewhat effective in combating cyanide poisoning.

Other methods to reduce exposure include:

- Use amyl nitrate capsules as antidote if symptoms develop.
- Employees should be trained regularly in emergency measures for cyanide poisoning and in CPR.
- A cyanide antidote kit must be rapidly available and ingredients replaced every 1-2 years to ensure freshness.
- Medical personnel trained in treatment of cyanide poisoning should be quickly available
- Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not used, respiratory protection should be mandatory.
- Always ensure that proper protective clothing is worn when using chemical substances and that personnel are trained in its use, care, and maintenance.
- Wash thoroughly immediately after exposure to methylacrylonitrile and at the end of the work shift or before eating, drinking, or smoking.
- Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of methylacrylonitrile should be communicated to all exposed and potentially exposed workers.

RISK ASSESSMENT: ENVIRONMENT

General Assessment

The environment is at risk of exposure during transportation, storage, disposal, or destruction of methylacrylonitrile. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance. Accidental spills, large or small, can result in fire, explosion, and possible contamination of the surrounding environmental mediums (water, soil, and air).

Methylacrylonitrile is considered a highly flammable liquid. Because of its low flash point and high boiling point, it is classified as a Class 1B flammable liquid (per OSHA 29 CFR 1910.106). It is also a dangerous fire and explosion hazard, highly reactive, and it polymerizes easily. These characteristics require special consideration during any emergency situation involving a leak or spill of methylacrylonitrile. Should methylacrylonitrile ever come into contact with incompatible substances such as oxidizers, acids,

bases, bromine, and amines either during use, transportation, or storage, the formation of highly toxic and/or highly explosive commodities is extremely possible.

The proper disposal/destruction method for methacrylonitrile is to burn it in a chemical incinerator equipped with an afterburner and air scrubber.

Methacrylonitrile can enter the environment through industrial effluents and through spills.

☠ *Acute Ecological Effects*

Acute (short-term) toxic effects may include the death of animals, birds, or fish and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to methacrylonitrile.

This chemical has high acute toxicity to aquatic life. Insufficient data are available to evaluate or predict the short-term effects of methacrylonitrile to plants, animals, or birds.

🕒 *Chronic Ecological Effects*

Chronic toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals.

Methacrylonitrile has high chronic toxicity in aquatic life. Insufficient data are available on the long-term effects of methacrylonitrile to plants, birds, or land animals.

💧 *Water Solubility*

Methacrylonitrile is moderately soluble in water. Concentrations of 1 to 1000 milligrams will mix with a liter of water.

🕒 *Persistence in the Environment*

Methacrylonitrile is slightly persistent in water, with a half-life of between 2 to 20 days. The half-life of a pollutant is the amount of time it takes for one half of the chemical to be degraded.

🐟 *Bioaccumulation in Aquatic Organisms*

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become con-

centrated in the tissues and internal organs of animals as well as humans.

The concentration of methacrylonitrile found in fish tissues is expected to be somewhat higher than the average concentration of methacrylonitrile in the water from which the fish was taken.

🛡️ *Recommended Risk-Reduction Measures*

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in a leak or spill to the environment. The correct use of DOT labeling (per the MSDS) on all containers, trucks, and rail cars will enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of methacrylonitrile should be segregated from incompatible chemicals to minimize the risk of cross-contamination or contact. Buildings designated for storage should be equipped with appropriate fire protection systems (alarms, sprinklers, emergency lighting, portable extinguishers).

If a spill or leak to the environment has occurred, fire department, emergency response and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those trained in proper spill containment procedures using non-sparking tools. Contaminated soils should be removed for incineration and replaced with clean soil. If methacrylonitrile should contact the water table, aquifer, or navigable waterway, time is of the essence. It is moderately soluble in water and, therefore, total containment and remediation may not be possible. When such spills occur, the local and/or state emergency response authorities must be notified. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of methacrylonitrile. If methacrylonitrile is spilled or leaked, the following specific steps are recommended:

- ☑ Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened for normal work.
- ☑ Remove all ignition sources.
- ☑ Ventilate area of spill or leak.
- ☑ Absorb liquids in vermiculite, dry sand, earth, or a similar material and deposit in sealed containers.
- ☑ Keep methacrylonitrile out of a confined space, such as a sewer, because of the possibility of ex-

plosion (unless the sewer is designed to prevent the buildup of explosive concentrations).

- ☑ It may be necessary to dispose of methylacrylonitrile as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving methylacrylonitrile can present a significant threat to business operations. The loss or damage of equipment or facilities can significantly affect fiscal viability. Lawsuits that may result from personnel injury/death, public exposures, and/or environmental contamination will also require a serious expenditure of resources. Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business.

Recommended Risk-Reduction Measures

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures dealing with safety or emergency response. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

SECTION I - GENERAL INFORMATION

| | | |
|--|--|---------------------------------|
| Characterization Alcohol | RCRA Number U154 | EPA Class Toxic Waste |
| DOT Proper Shipping Name Methyl alcohol | Chemical Abstract Service (CAS) Number 67-56-1 | |
| DOT Hazard Class and Label Requirements Flammable Liquid; Poison | DOT Emergency Guide Code 28 | |
| DOT Identification Number UN 1230 | Chemical Formula CH₃OH | |

Synonyms

Carbinol; Columbian spirits; methanol; pyroligneous spirit; wood alcohol; wood naphtha; wood spirit.

SECTION II - HAZARDOUS INGREDIENTS AND IDENTITY INFORMATION

| Hazardous Components (specific identity) | OSHA Exposure Criteria | NIOSH Exposure Criteria | Immediately Dangerous to Life and Health (IDLH) | ACGIH Exposure Criteria |
|---|---|--|---|---|
| Methyl alcohol (derivation: By high-pressure catalytic synthesis from carbon monoxide and hydrogen; partial oxidation of natural gas hydrocarbons; by gasification of wood, peat, and lignite; from methane with molybdenum catalyst). 1 ppm = 1.33 mg/m³ | PEL (skin): 200 ppm 260 mg/m³ STEL (15-min): 250 ppm 310 mg/m³ | REL (skin): 200 ppm 260 mg/m³ STEL: 250 ppm 325 mg/m³ | 6000 ppm | TLV: 200 ppm 262 mg/m³ STEL: 250 ppm 328 mg/m³ |

SECTION III - PHYSICAL AND CHEMICAL CHARACTERISTICS

| | |
|--|--|
| Boiling Point 148°F (64°C) | Specific Gravity (H ₂ O = 1) 0.79 |
| Vapor Pressure (mm Hg) 29 at 68°F (20°C) | Molecular Weight 46.1 |
| Vapor Density (Air = 1) 1.11 | Melting Point -144°F (-98°C) |

Solubility

Soluble in water, ethanol, alcohols, ether, benzene, ketones, and most organic solvents.

Appearance and Odor

Clear, colorless liquid with a characteristic, pungent odor. Odor Threshold = 10 ppm.

SECTION IV - FIRE AND EXPLOSION HAZARD DATA

| | |
|--|---|
| Flash Point (method used) 54°F (12°C) closed cup | Explosive Limits in Air % by Volume LEL: 6.0% UEL: 36% |
| NFPA Classification Class IB Flammable Liquid | Autoignition Temperature 878°F (470°C) |

Extinguishing Media

Dry chemical, carbon dioxide, alcohol resistant foam, water spray (use as fog in flooding quantities).

Special Fire Fighting Procedures

Poisonous gases are produced in fire. Wear full protective clothing and self-contained breathing apparatus (SCBA). Continue to cool containers with water after fire is extinguished. Move containers from fire area if it can be done without risk. For large fires, use unmanned hose apparatus, if possible. Evacuate non-essential personnel 1500 feet radius if fire. Consider down-wind conditions.

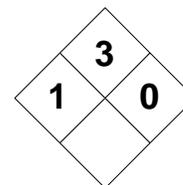

Unusual Fire and Explosion Hazards

Vapors are heavier than air and may travel a distances to ignition source to flashback. Vapors may explode if ignited in an enclosed area.

| SECTION V - REACTIVITY DATA | | | | |
|---|--|--|--|---|
| Stability | | Conditions to Avoid Methyl alcohol is stable under normal conditions of storage and operation. Avoid contact with incompatible materials. Keep away from heat, flame, and other ignition sources. | | |
| Stable X | Unstable | Incompatibility (materials to avoid) Reacts violently in contact with oxidizers (bromine, chlorine, fluorine), beryllium dihydride, metals (potassium, magnesium), potassium tertbutoxide, carbon tetrachloride + metals, chloroform + heat. | | |
| Hazardous Polymerization | | Conditions to Avoid Under normal conditions of temperature and pressure, methyl alcohol is not expected to undergo hazardous polymerization. | | |
| May Occur | Will Not Occur X | Hazardous Decomposition or By-products When heated to decomposition, methyl alcohol emits acrid and irritating fumes, including oxides of carbon (monoxide and dioxide) and formaldehyde. | | |
| SECTION VI - HEALTH HAZARD DATA | | | | |
| Primary Route(s) of Entry: | | Inhalation? X | Absorption (skin)? X | Ingestion? X |
| Health Hazards INHALATION: Irritation of the eyes, nose, throat, and respiratory tract. CNS effects include headache, nausea, visual disturbances and impairment (optic nerve damage can progress up to and including permanent blindness), acidosis, convulsions, circulatory collapse, respiratory failure, and death. ABSORPTION: As a solvent, cause skin dryness, cracking, and possible dermatitis. Eye contact can result in burning, stinging, tearing, corneal injury, and painful photophobia. Absorption leads to systemic effects similar to inhalation. INGESTION: Gastrointestinal irritation, kidney and brain effects, and similar effects to inhalation. | | | | |
| Carcinogenicity Unknown Human Unknown Animal | NTP Listed? No | IARC Cancer Review Group? No | OSHA Regulated? 29 CFR 1910.1000 Table Z-1 | Target Organs? Skin, eyes, CNS, respiratory system, GI tract. |
| Medical Conditions Generally Aggravated by Exposure Existing visual disorders or disturbances may be quickly aggravated by exposure to methyl alcohol. | | | | |
| Emergency and First-aid Procedures Eye contact: Flush immediately with water for 15 minutes (minimum); seek medical attention. Skin contact: Remove all contaminated clothing. Immediately wash area with large amounts of soap and water. Seek medical assistance. For inhalation: Remove the person from exposure. Provide respiratory assistance and CPR. Transfer to medical facility. If swallowed: Seek medical attention immediately. Give 1-2 glasses of water and induce vomiting. Seek medical attention immediately. | | | | |
| SECTION VII - PRECAUTIONS FOR SAFE HANDLING AND USE | | | | |
| Steps to be Taken in Case Material is Released or Spilled Full protective clothing required with SCBA. Contain spills using absorbent material (vermiculite or other). Ventilate area of spill and remove all ignition sources. Have extinguishing agent available in case of fire. Store materials in DOT-approved containers. | | | | |
| Preferred Waste Disposal Method Incineration in chemical incinerator equipped with scrubber and afterburner. | | | | |
| Precautions to be Taken in Handling and Storage Store in tightly closed containers in a cool, dark, well-ventilated area. Protect containers from physical damage. Keep heat, fire, and flame away. Outside building or underground storage is recommended. | | | | |
| Other Precautions and Warnings Ground and bond all metal containers. Ensure explosion-proof electrical installations. | | | | |
| SECTION VIII - CONTROL MEASURES AND PERSONAL PROTECTIVE EQUIPMENT | | | | |
| Respiratory Protection (specify type) For vapor exposures, use an organic vapor air-purifying respirator. Greater protection is obtained using a supplied-air respirator or a self-contained breathing apparatus (SCBA) with full facepiece operated in pressure demand or other positive pressure mode. | | | | |
| Ventilation Local exhaust or general mechanical systems recommended. | | | | |
| Protective Gloves Impervious Rubber Gloves | Eye Protection Chemical Goggles or Face Mask | Other Protective Clothing Impermeable Apron or Protective Suit | | |
| Work/Hygiene Practices Always wash hands thoroughly after using chemical; never bring food, drink, or smoking materials into vicinity of chemicals. | | | | |

METHYL ALCOHOLCH₃OH

CAS: 67-56-1

**IDENTIFICATION AND TYPICAL USES**

Methyl alcohol is a colorless or clear liquid with a characteristic pungent odor. It is used in the manufacture of formaldehyde, acetic acid, and dimethyl terephthalate. Also used in chemical synthesis of methyl amines, methyl chloride, and methylacrylate. Used in antifreeze, as an octane booster for gasoline, as a solvent for nitrocellulose, ethylcellulose, polyvinyl butyral, shellac, rosin, manila resin, and dyes. Also a denaturant for ethanol, a dehydrator for natural gas, a fuel for utility plants (methyl fuel), in feedstock for manufacture of synthetic proteins by continuous fermentation, as a source of hydrogen for fuel cells, and a home heating oil extender.

RISK ASSESSMENT: HEALTH**General Assessment**

The toxicity of methyl alcohol is much higher in comparison to ethanol. Methyl alcohol is toxic to humans by all routes of exposure (*ingestion, inhalation, and dermal absorption*). Once in the body, methyl alcohol oxidizes to formaldehyde and formic acid. The toxicity of methyl alcohol is attributed primarily to the metabolites of these two toxic compounds. It is a narcotic. There are no report regarding its carcinogenic potential. However, it has caused mutations (genetic changes) and is an experimental teratogen and reproductive toxin.

Inhalation can cause irritation of the eyes, nose, throat, upper respiratory tract, and associated mucosa. There may be significant action on the nervous system, especially the optic nerve with damage progressing up to and including blindness. Other central nervous system effects include headache, nervousness, tremors, acidosis, convulsions, dizziness, tearing, fatigue, nausea, somnolence, narcosis with stupor and loss of consciousness, circulatory system collapse, respiratory failure, and death.

Liquid contact with the eyes causes immediate burning and stinging with lachrymation and reflex closure, and inflammation of the lids with painful photophobia. Skin contact results in drying and cracking which can lead to secondary infections and dermatitis. Dermal absorption causes many of the symptoms of inhalation. A combined absorption exposure with inhalation or ingestion can present a life-threatening exposure risk.

Ingestion of methyl alcohol affects the brain, lungs, kidney, gastrointestinal tract, eyes, and respiratory system and can cause coma, blindness, and death.

☠ Acute Health Effects

The following acute (short-term) health effects may occur immediately or shortly after exposure to methyl alcohol:

- Skin:** Causes dryness and cracking leading to dermatitis and possible infection. Absorption can occur quickly causing toxic systemic effects.
- Eye:** Severe irritation with burning and stinging with possible damage to the cornea and conjunctiva.
- Lung:** Irritation of the eyes, nose, throat, and respiratory tract.
- CNS:** High concentrations can cause depression of the CNS with symptoms of sleepiness and lack of concentration.

☘ Chronic Health Effects

The following chronic (long-term) health effects may occur at some time after exposure to methyl alcohol and can last for months or even years:

Cancer Hazards: According to information presented in the references, methyl alcohol has not been shown to cause cancer in test animals. However, human

mutation data have been reported and many scientists believe that exposure to such chemicals may pose a cancer risk in the long-term.

Reproduction: According to the references, methyl alcohol may affect reproduction as well as adversely affect a developing fetus.

Other Chronic Effects: Very high or prolonged exposure may result in mucous membrane irritation, headache, and depression of the CNS with symptoms of somnolence and lack of concentration. Chronic inhalation or skin absorption may lead to visual impairment or even complete blindness.

🕒 **Recommended Risk-Reduction Measures**

Industrial exposures to methyl alcohol by all routes must be avoided. The best risk reduction measure is to use a less toxic chemical as a substitute for a methyl alcohol. However, substitution may not always be an alternative. Therefore, *engineering controls* are the most effective methods of reducing exposures. The best protection is to enclose operations and/or provide local, explosion-proof exhaust ventilation at the site of chemical release. While not always operationally feasible, isolating operations can also reduce exposure risk.

Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around methyl alcohol. For concentrations over the PEL (200 ppm), an air-purifying respirator with an organic vapor cartridge will suffice. For higher concentrations, exposures in confined spaces, or when the exposure level is unknown (as in an emergency), a supplied-air respirator with full facepiece operated in positive pressure mode, or a self-contained breathing apparatus (SCBA) with full facepiece and operated in pressure demand mode are the recommended respiratory protection methods of choice. If a full facepiece is not available, then chemical goggles should be worn to protect the eyes. Whenever a chemical splash hazard exists, a face shield and a protective apron should be worn. To prevent hand and skin exposures, impervious gloves should be used. Glove manufacturers should be contacted and permeation studies obtained *before* final glove selections have been made.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with methyl alcohol.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where methyl alcohol is used or stored.

If symptoms develop or overexposure is suspected, the following medical tests are recommended:

- ☑ Urinalysis, including pH (lowered when poisoning has occurred) and formic acid excretion.
- ☑ Blood pH and plasma bicarbonate.
- ☑ Hemodialysis may be helpful treatment for severe poisoning. Ethyl alcohol may be partially effective as an antidote (it appears to compete with methyl alcohol to inhibit its oxidation in the body).
- ☑ Treat severe acidosis by oral administration of sodium bicarbonate and magnesium sulfate, or by intravenous administration of sodium bicarbonate.

Any medical evaluation should include a careful history of past and present symptoms with an examination. Medical tests that look for existing damage are not a substitute for controlling exposures.

Other methods to reduce exposure include:

- ☑ Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not used, respiratory protection should be mandatory.
- ☑ Always ensure that proper protective clothing is worn when using chemical substances.
- ☑ Wash thoroughly immediately after exposure to methyl alcohol and at the end of the work shift or before eating, drinking, or smoking.
- ☑ Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of methyl alcohol should be communicated to all exposed or potentially exposed workers.

RISK ASSESSMENT: ENVIRONMENT

General Assessment

The environment is at risk of exposure during transportation, storage, disposal, or destruction of methyl alcohol. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance. Accidental spills, large or small, can result in fire, explosion, and possi-

ble contamination of the surrounding environmental mediums (water, soil, and air).

Methyl alcohol is considered a Class IB flammable liquid (according to OSHA 29 CFR 1910.106). Its low flash point and relatively low boiling point present a serious fire and explosion hazard concern. Also, because it is incompatible with a number of common materials, especially strong oxidizers, and contact can result in violent and explosive reactions. It can form explosive mixtures in air and can ignite on contact with heat, fire, or sparks. It will react and then explode in contact with chloroform + heat. It also reacts violently with alkyl aluminum salts, acetyl bromide, nitric acid, and many other compounds. These characteristics require special consideration during any emergency situation involving a leak or spill of methyl alcohol.

Methyl alcohol can enter the environment through unchecked industrial discharges into effluents and through spills.

☠ *Acute Ecological Effects*

Acute (short-term) toxic effects may include the death of animals, birds, or fish, and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to methyl alcohol.

This chemical has slight acute toxicity to aquatic life. It has caused germination and size decrease, and other injury to agricultural and ornamental crops. Insufficient data are available to evaluate or predict the short-term effects of methyl alcohol to birds or terrestrial animals.

🕒 *Chronic Ecological Effects*

Chronic toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals.

Methyl alcohol has slight chronic toxicity to aquatic life. Insufficient data are available to evaluate or predict the long-term effects of methyl alcohol to plants, birds, or land animals.

💧 *Water Solubility*

Methyl alcohol is highly soluble in water. Concentrations of 1000 milligrams and more can be expected to mix with a liter of water.

🕒 *Persistence in the Environment*

Methyl alcohol is slightly persistent in water, with a half-life of between 2 to 20 days. The half-life of a pollutant is the amount of time it takes for one-half of the chemical to be degraded. About 86.5% of methyl alcohol will eventually end up in the water; the remainder will end up in air.

🐟 *Bioaccumulation in Aquatic Organisms*

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans. The concentration of methyl alcohol found in fish tissues is expected to be about the same as the average concentration of methyl alcohol in water from which the fish was taken.

🛡️ *Recommended Risk-Reduction Measures*

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in a leak or spill to the environment. The correct use of DOT labeling (per the MSDS) on all containers, trucks, and rail cars will enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of methyl alcohol should be segregated from incompatible chemicals to minimize the risk of cross-contamination or contact. Buildings designated for storage should be equipped with appropriate fire protection systems (alarms, sprinklers, emergency lighting, portable extinguishers). Equipment should be designed to meet explosion-proof standards.

If a spill or leak to the environment has occurred, fire department, emergency response, and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those trained in proper spill containment procedures using non-sparking tools. Contaminated soils should be removed for incineration and replaced with clean soil. If methyl alcohol should contact the water table, aquifer, or navigable waterway, time is of the essence. It is highly soluble in water and, therefore, total containment and remediation may not be possible. When such spills occur, the local and/or state emergency response authorities should be notified. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of methyl alcohol. If methyl alcohol is spilled or leaked, the following specific steps are recommended:

Risk Management for Hazardous Chemicals

- ☑ Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened for normal work.
- ☑ Ventilate area and remove ignition sources.
- ☑ Absorb liquids in vermiculite, dry sand, earth, or a similar material and deposit in sealed containers. Use non-sparking tools.
- ☑ It may be necessary to dispose of methyl alcohol as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS***General Assessment***

Accidents or mishaps involving methyl alcohol can present a moderate threat to business operations. The loss or damage of equipment or facilities can significantly affect fiscal viability. Lawsuits that may result from personnel injury/death, public exposures, and/or environmental contamination will also require a serious expenditure of resources. Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business.

🕒 *Recommended Risk-Reduction Measures*

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures or policies intended to manage the use of chemicals in the workplace. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

|--|--|
| Flash Point (method used) 34°F (1.1°C) - liquid; 14°F (-10°C) - gas (CC) | Explosive Limits in Air % by Volume LEL: 4.9% UEL: 20.7% |
| NFPA Classification Flammable Gas or Class 1A Flammable Liquid | Autoignition Temperature 806°F (430°C) |

Extinguishing Media

Stop flow of gas first (if possible). If liquid, use foam, carbon dioxide, or dry chemical.

Special Fire Fighting Procedures

Methylamine is an extremely flammable, very dangerous fire and explosion hazard. Poisonous gases are evolved from fire. Wear a self-contained breathing apparatus with full facepiece. Ensure ALL sources of escaping gas are controlled. Move containers from fire area if it can be done without risk. Water may be ineffective on fire. Cool containers with water until long after fire is out.

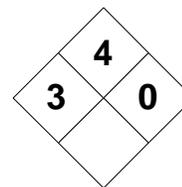

Unusual Fire and Explosion Hazards

Gas is explosive. Containers may explode in flame. Vapors are heavier than air and will travel for a great distance to an ignition source and flashback to cause fire or explosion.

| SECTION V - REACTIVITY DATA | | | | |
|--|----------------------------|--|--|---|
| Stability | | Conditions to Avoid Methylamine is normally stable in its closed containers, during routine operations (those that do not expose it to ignition sources). Avoid contact with heat, sparks, flame, and other sources of ignition. | | |
| Stable X | Unstable | Incompatibility (<i>materials to avoid</i>) Incompatible with strong oxidizing materials (bromine, chlorine, fluorine, peroxides, permanganates), and mercury. Corrosive to copper and zinc alloys, aluminum, and galvanized surfaces. | | |
| Hazardous Polymerization | | Conditions to Avoid Under normal conditions of temperature and pressure, hazardous polymerization of methylamine is not expected to occur. | | |
| May Occur | Will Not Occur X | Hazardous Decomposition or By-products If involved in fire, methylamine can produce toxic oxides of carbon and nitrogen, and ammonia derivatives. | | |
| SECTION VI - HEALTH HAZARD DATA | | | | |
| Primary Route(s) of Entry: | | Inhalation? X | Absorption (skin)? X (liquid) | Ingestion? X (liquid) |
| Health Hazards INHALATION: Vapors are irritating to the eyes, skin, and respiratory tract. Causes pulmonary edema (fluid in the lungs), which is a medical emergency and can lead to death. There may also be blurred or hazy vision (temporary) resulting from corneal epithelium. SKIN & EYES: Contact with the compressed gas or liquid can cause frostbite and first degree burns. INGESTION: Not likely since methylamine is a gas at normal room temperatures. If it occurs, there can be severe burns of the mouth and stomach that can be fatal. | | | | |
| Carcinogenicity Unknown Human Unknown Animal | NTP Listed? No | IARC Cancer Review Group? No | OSHA Regulated? 29 CFR 1910.1000 Table Z-1 | Target Organs? Eyes, skin, respiratory system |
| Medical Conditions Generally Aggravated by Exposure None Reported. | | | | |
| Emergency and First-aid Procedures Eye contact: For frostbite, rinse with warm (104°F/40°C) water. Skin contact: Remove all contaminated clothing. Immediately wash area with large amounts of warm (104°F/40°C) water. For inhalation: Remove the person from exposure. Provide respiratory assistance and CPR. Transfer promptly to medical facility. Observe for 24-48 hours for lung effects (pulmonary edema). If swallowed: Contact poison control center. Unless advised otherwise, give 1-2 glasses of water to dilute. Do NOT induce vomiting. | | | | |
| SECTION VII - PRECAUTIONS FOR SAFE HANDLING AND USE | | | | |
| Steps to be Taken in Case Material is Released or Spilled Remove all ignition sources. Ventilate area. Stop flow of gas. If the source of leak is a cylinder and cannot be stopped, remove to safe place in open air; repair leak or let cylinder empty. If gas has not yet ignited, use a water spray to knock down vapors and direct them from ignition source. | | | | |
| Preferred Waste Disposal Method None specified in the references (incineration of a gas may be the only alternative). | | | | |
| Precautions to be Taken in Handling and Storage Do not store with incompatible materials or in the presence of heat since violent reactions or explosions can occur. Store in tightly closed pressurized containers in a cool, dark, well-ventilated area away from sunlight. Keep away from ignition sources such as fire, sparks, and flame. | | | | |
| Other Precautions and Warnings Bulk storage of methylamine is not recommended. Containers may explode in fire or under conditions of extreme heat (do not store outdoors or in direct sunlight). | | | | |
| SECTION VIII - CONTROL MEASURES AND PERSONAL PROTECTIVE EQUIPMENT | | | | |

METHYLAMINE

CAS: 74-89-5

**IDENTIFICATION AND TYPICAL USES**

Methylamine is a colorless gas with a fish or ammonia-like odor. A liquid below 21°F (-6°C). It is normally shipped as a liquefied compressed gas. It is used as an intermediate for accelerators, dyes, pharmaceuticals, insecticides, fungicides, surface active agents, in tanning, for the dyeing of acetate textiles, as a fuel additive, and as a polymerization inhibitor. It is also used as a component in paint removers, solvents, as a photographic developer, and as a rocket propellant.

RISK ASSESSMENT: HEALTH***General Assessment***

Methylamine normally appears as a gas. As such, its primary route of entry into the body is through *inhalation*. Skin contact with the liquid can be destructive to tissues due to the extremely cold temperatures and irritating properties of methylamine, but absorption is not a likely exposure route. Since methylamine usually exists as a gas at room temperatures, ingestion is not likely under normal conditions. It is not known if exposure to methylamine will lead to carcinogenic or teratogenic effects in humans or animals. However, mutation data have been reported and caution is warranted in use and handling.

Inhalation of methylamine vapors causes irritation of the eyes, nose, throat, and respiratory tract. Exposure can lead to pulmonary edema (fluid buildup in the lungs) which is a medical emergency and can be fatal. Symptoms of congestion, cough phlegm, tightness and possibly pain in chest, and difficulty breathing may be delayed up to 48 hours thereby creating a false sense of security with regard to health hazard/exposure risk. There is also a possibility that exposure can cause blurred or hazy vision, apparently as a result of corneal epithelium disturbances.

Skin or eye contact with the vapor causes irritation. Liquid contact with either the skin or the eyes

causes serious irritation and even first degree burns with subsequent tissue damage, and frostbite.

Although ingestion is unlikely to occur under normal conditions (methylamine is a gas at room temperature), swallowing it will cause severe burns to the mouth and stomach and can lead to death.

☠ *Acute Health Effects*

The following acute (short-term) health effects may occur immediately or shortly after exposure to methylamine:

Skin: Redness, smarting, pain, possible dermatitis, first degree burns, and severe frostbite.

Eye: Causes frostbite, redness, irritation, severe pain, and blurred vision.

Lung: Vapor is seriously irritating and therefore poses a significant threat of damage to the lungs. Irritation can lead to pulmonary edema (fluid buildup in the lungs).

Other: Methylamine solutions are strongly alkaline and can cause deep tissue destruction.

☘ *Chronic Health Effects*

The following chronic (long-term) health effects may occur at some time after exposure to methylamine and can last for months or even years:

Cancer Hazards: According to information presented in the references, it is not known if exposure to methylamine will lead to carcinogenic or mutagenic effects. Mutation data have been reported and many scientists believe that exposure to such chemicals may pose a cancer risk in the long-term.

Reproductive Hazards: According to information presented in the references, methylamine has not been adequately tested for its ability to adversely affect reproduction in animals or humans. There are no reports to support any claims of reproductive hazards.

🛡 *Recommended Risk-Reduction Measures*

Personnel should avoid direct contact with methylamine. If a less toxic chemical cannot be substituted for a hazardous substance, then *engineering controls* are the most effective method of reducing exposures. The best protection is to separate operations and provide local exhaust ventilation at the site of chemical release. While not always operationally feasible, isolating operations can also reduce exposure. Using equipment with explosion-proof designs and ensuring all metal containers and tools are electrically grounded and bonded can further reduce the potential for injury or damage. Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with methylamine. For exposures above the PEL (10-ppm), use an MSHA/NIOSH-approved chemical cartridge respirator with a full facepiece and cartridges suitable for protection against amines. For higher or more frequent exposures, use an powered supplied-air respirator operated in pressure demand or other positive pressure mode, or a self-contained breathing apparatus (SCBA) with full facepiece operated in pressure demand mode. If a full facepiece is not available, then chemical goggles should be worn to protect the eyes. Whenever a chemical splash hazard exists, a face shield and a rubber or leather apron should be worn. To prevent hand and skin exposures with the liquid, thermal gloves should be used. Glove manufacturers should be contacted and consulted *before* final glove selections have been made.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with methylamine.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where methylamine is used or stored. Before beginning employment and at regular intervals thereafter (e.g., annually), the following medical tests are recommended:

- Lung function tests (establish baseline).

If symptoms develop or overexposure is suspected, the following additional tests may be helpful:

- Lung function tests (compare to baseline).
- Consider chest X-ray after acute overexposure (may be negative if taken immediately following exposure due to delayed onset of pulmonary edema).

Other methods to reduce exposure to chemicals include:

- Where possible, use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not used, respiratory protection should be mandatory.
- Prevent static sparks by electrically grounding and bonding all equipment used with or around methylamine.
- Always ensure that proper protective clothing is worn when using chemical substances.
- Wash thoroughly immediately after exposure to methylamine and at the end of the work shift or before eating, drinking, or smoking.
- Safety shower and eyewash stations should be readily available in work areas where methylamine is used or stored.
- Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of methylamine should be communicated to all exposed and potentially exposed workers.

RISK ASSESSMENT: ENVIRONMENT

General Assessment

The environment is at risk of exposure during transportation, storage, disposal, or destruction of methylamine. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance. Accidental releases, large or small, can result in fire, explosion, and possible contamination of the surrounding environmental mediums (water, soil, and air).

Methylamine is an extremely flammable and highly explosive gas. As a liquid, it is considered a Class 1A flammable liquid (per OSHA 29 CFR 1910.106). Its extremely low flash point and boiling point present a serious fire hazard. Also, since it can react violently in the presence of oxidizers, such as chlorine, methylamine requires special consideration during any emergency involving a leak or release of methylamine gas or liquid.

Methylamine can enter the environment through industrial discharges, unchecked venting to air, or through spills of the liquid.

Acute Ecological Effects

Acute (short-term) toxic effects may include the death of animals, birds, or fish, and death or low growth rate

in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to methylamine. Insufficient data are available on the short-term effects of methylamine on aquatic life, plants, birds, or land animals.

☪ *Chronic Ecological Effects*

Chronic (long-term) toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals. Insufficient data are available to evaluate the long-term effects of methylamine to aquatic life, plants, birds, or land animals.

◆ *Water Solubility*

Methylamine is highly soluble in water. Concentrations of 1000 milligrams and more will mix with a liter of water.

⌚ *Persistence in the Environment*

Methylamine is slightly persistent in the aquatic environment with a half-life of 2 to 20 days. The half-life of a pollutant is the amount of time it takes for one half of the chemical to be degraded.

🌊 *Bioaccumulation in Aquatic Organisms*

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans.

Methylamine is not expected to accumulate in the tissues of fish.

🚫 *Recommended Risk-Reduction Measures*

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in a leak or release to the environment. The correct use of DOT labeling (per the MSDS) on all containers, trucks, and rail cars will enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of methylamine should be segregated from incompatible chemicals to minimize the risk of cross-contamination or contact. Buildings designated for storage should be equipped with appropriate fire protection systems (alarms, sprinklers, emergency lighting, portable extinguishers).

If a spill or release to the environment has occurred, fire department, emergency response, and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those trained in proper containment procedures. Leaking cylinders must be repaired or removed to a safe location and allowed to vent until empty. Contaminated soils should be removed for incineration and replaced with clean soil. If methylamine should contact the water table, aquifer, or navigable waterway, time is of the essence. It is readily miscible in water and total containment and remediation may not be possible. When such spills occur, it may be necessary to contact the local and/or state emergency response authorities. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of methylamine. If methylamine is spilled or leaked, the following specific steps are recommended:

- ☑ Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened for normal work.
- ☑ Remove all ignition sources.
- ☑ Ventilate area of spill or leak.
- ☑ If applicable, stop flow of leaking liquid or gas. If leak source is a cylinder and the leak cannot be stopped in place, remove leaking cylinder to a safe place in the open air, and repair or allow cylinder to empty. Use water spray to knock down vapors and to protect emergency response personnel attempting to shut off leak.
- ☑ Keep methylamine out of a confined space, such as a sewer, because of the possibility of explosion (unless the sewer is designed to prevent the buildup of explosive concentrations).

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving methylamine can present a significant threat to business operations. The loss or damage of equipment or facilities can significantly affect fiscal viability. Lawsuits that may result from personnel injury, public exposures, and environmental contamination will also require a serious expenditure of resources. Media attention surrounding an injury, illness, or environmental damage can also result in a loss of profits and loss of current as well as future business.

Recommended Risk-Reduction Measures

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures dealing with safety or emergency response. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

| DOT Hazard Class and Label Requirements Combustible Liquid | DOT Emergency Guide Code 26 | |
| DOT Identification Number UN 1110 | Chemical Formula CH₃CO[CH₂]₄CH₃ | |

Synonyms

Amyl methyl ketone; *n*-amyl methyl ketone; 2-heptanone; methyl pentyl ketone.

SECTION II - HAZARDOUS INGREDIENTS AND IDENTITY INFORMATION

| Hazardous Components (specific identity) | OSHA Exposure Criteria | NIOSH Exposure Criteria | Immediately Dangerous to Life and Health (IDLH) | ACGIH Exposure Criteria |
|---|--|--|---|---|
| Methyl <i>n</i>-amyl ketone (derivation: By catalytic dehydration of 2-heptanol or by decomposition of ethyl butylacetate. Occurs naturally in oil of clove and cinnamon bark oil and also causes the peppery odor of Roquefort cheese). 1 ppm = 4.75 mg/m³ | PEL: 100 ppm 465 mg/m³ STEL: Not Established | REL: 100 ppm 465 mg/m³ STEL: Not Established | 800 ppm | TLV: 50 ppm 233 mg/m³ STEL: Not Established |

SECTION III - PHYSICAL AND CHEMICAL CHARACTERISTICS

| | |
|---|--|
| Boiling Point 305°F (152°C) | Specific Gravity (H ₂ O = 1) 0.81 |
| Vapor Pressure (mm Hg) 3 at 69°F (20°C) | Molecular Weight 114 |
| Vapor Density (Air = 1) 4.97 | Freezing Point -31°F (-35°C) |

Solubility

Slightly soluble (0.4%) in water. Soluble in benzene, ethanol, diethyl ether, and most organic solvents.

Appearance and Odor

Colorless or water-white liquid with a spicy, banana-like odor and pear-like taste.

SECTION IV - FIRE AND EXPLOSION HAZARD DATA

| | |
|---|--|
| Flash Point (method used) 102°F (39°C) closed cup | Explosive Limits in Air % by Volume LEL: 1.1% at 151°F UEL: 7.9% at 250°F |
| NFPA Classification Class II Combustible Liquid | Autoignition Temperature 991°F (532°C) |

Extinguishing Media

Large fires: Alcohol foam or water spray. Small fires: Dry chemical, carbon dioxide, water spray, foam.

Special Fire Fighting Procedures

Poisonous gases are produced in fire. Wear full protective clothing and self-contained breathing apparatus. Fight fire from a distance if possible. Keep fire-exposed containers cool with water spray. A solid stream of water may spread fire. If it can be done safely, move fire-exposed containers from area.

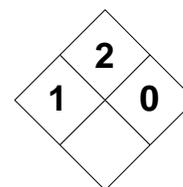

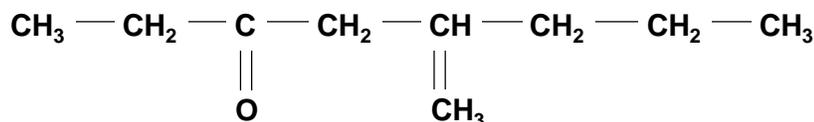

Unusual Fire and Explosion Hazards

Containers may explode in fire due to the buildup of internal pressures. BLEVE (boiling liquid expanding vapor explosion) is possible. Immediately evacuate if rising sound is heard from venting device or a noticeable discoloration is observed on the sides of the tank or storage vessel.

| SECTION V - REACTIVITY DATA | | | | |
|--|--|---|--|--|
| Stability | | Conditions to Avoid Normally stable. Do not allow methyl n-amyl ketone to come into contact with incompatible materials. Avoid contact with fire or high heat sources. Do not use in confined spaces. | | |
| Stable X | Unstable | Incompatibility (<i>materials to avoid</i>) Incompatible with strong oxidizers (bromine, chlorine, fluorine), alkalis, and strong acids. It will also attack some forms of plastic. | | |
| Hazardous Polymerization | | Conditions to Avoid Under normal conditions of temperature and pressure, hazardous polymerization of methyl n-amyl ketone is not expected to occur. | | |
| May Occur | Will Not Occur X | Hazardous Decomposition or By-products When heated to decomposition, methyl n-amyl ketone emits acrid, irritating smoke and fumes, including oxides of carbon. | | |
| SECTION VI - HEALTH HAZARD DATA | | | | |
| Primary Route(s) of Entry: | | Inhalation? X | Absorption (skin)? | Ingestion? X |
| Health Hazards | | | | |
| INHALATION: Irritation of the mucosa of the respiratory tract causing respiratory depression with gasping, choking, and dyspnea. Higher concentrations causes CNS depression with headache, dizziness, fainting, tremor, chemical pneumonitis, coma, and possibly death. | | | | |
| SKIN & EYES: Skin contact with liquid or vapor can result in irritation and may cause dermatitis and paresthesia (tingling). Eye contact causes pain, irritation, corneal damage, and tearing. | | | | |
| INGESTION: Unlikely. Symptoms of irritation, sore throat, nausea, coughing, salivation, vomiting. | | | | |
| Carcinogenicity Unknown Human Unknown Animal | NTP Listed? No | IARC Cancer Review Group? No | OSHA Regulated? 29 CFR 1910.1000 Table Z-1 | Target Organs? Respiratory system; skin; eyes; CNS, PNS. |
| Medical Conditions Generally Aggravated by Exposure Skin conditions (dermatitis) may be aggravated. | | | | |
| Emergency and First-aid Procedures | | | | |
| Eye contact: Immediately flush with large amounts of water for 15 minutes (minimum), occasionally lifting eyelids. Skin contact: Remove all contaminated clothing. Immediately wash area with large amounts of soap and water. For inhalation: Remove the person from exposure. Provide respiratory assistance and CPR. Transfer promptly to medical facility. If swallowed: Seek medical attention immediately. Give a conscious and alert victim several glasses of milk or water. The decision to induce vomiting must be carefully considered (it may cause aspiration of the liquid leading to pneumonitis). | | | | |
| SECTION VII - PRECAUTIONS FOR SAFE HANDLING AND USE | | | | |
| Steps to be Taken in Case Material is Released or Spilled | | | | |
| Remove all ignition sources. Restrict persons not wearing protective equipment from entering area of spill or leak until cleanup is complete. Ventilate area. Absorb liquid in dry sand or other material and deposit in sealed containers. Damp mop residue. Alert appropriate state or federal response agencies. | | | | |
| Preferred Waste Disposal Method | | | | |
| Burn in a chemical incinerator equipped with an afterburner and scrubber. | | | | |
| Precautions to be Taken in Handling and Storage | | | | |
| Do not store with incompatible chemicals since violent reactions can occur. Store in tightly closed containers in a cool, dark, well-ventilated area away from fire, sparks, and flame. Use non-sparking tools on containers. Ground and bond metal containers during transfer operations. | | | | |
| Other Precautions and Warnings | | | | |
| Containers may explode in fire or under conditions of extreme heat (do not store outdoors or in direct sunlight). Protect containers from physical damage. | | | | |
| SECTION VIII - CONTROL MEASURES AND PERSONAL PROTECTIVE EQUIPMENT | | | | |
| Respiratory Protection (<i>specify type</i>) | | | | |
| Exposures above 100 ppm: MSHA/NIOSH-approved full-facepiece respirator with organic vapor cartridge. Greater protection is obtained from a self-contained breathing apparatus (SCBA) with full face-piece and pressure demand or other positive pressure mode. | | | | |
| Ventilation | | | | |
| Local exhaust or general mechanical systems recommended. | | | | |
| Protective Gloves Impervious Materials | Eye Protection Chemical Goggles and/or Face Mask | Other Protective Clothing Protective Apron | | |
| Work/Hygiene Practices | | | | |
| Always wash hands thoroughly after using chemical; never bring food, drink, or smoking materials into vicinity of chemicals. | | | | |

METHYL *n*-AMYL KETONE

CAS: 110-43-0

**IDENTIFICATION AND TYPICAL USES**

Methyl *n*-amyl ketone is a colorless or watery-white liquid with a spicy, banana-like odor and a pear-like taste. It is used as a solvent for nitrocellulose lacquers and synthetic resins, and as a flavoring agent in food and drink. It is also sometimes used as scenting agent in perfumes.

RISK ASSESSMENT: HEALTH***General Assessment***

Methyl *n*-amyl ketone is moderately toxic to humans by *inhalation* and *ingestion*. There are no reports in the references that indicate dermal absorption is a risk factor. However, skin or eye contact can cause surface tissue damage and inflammation. The references contain no information on the carcinogenic, mutagenic, or teratogenic properties of methyl *n*-amyl ketone. Overexposure to this compound is not common. Its irritating properties and penetrating odor are usually present at levels low enough to serve as a warning to personnel.

Inhalation of methyl *n*-amyl ketone causes irritation of the mucosa of the respiratory tract leading to respiratory depression with symptoms of gasping, choking, and dyspnea. Exposure to higher concentrations can cause depression of the central nervous system (CNS) with symptoms of headache, lachrymation, somnolence, decreased breathing, dizziness, fainting, tremor, coma, and possibly death (rare but possible). If the liquid should be aspirated, it can lead to chemical pneumonitis.

Skin contact with the liquid or vapor can lead to chemical dermatitis and localized paresthesia with symptoms of prickling or tingling with no apparent stimulus and associated sensory nerve damage. Eye contact causes irritation with lachrymation and, in

prolonged contact, may lead to ocular pain, corneal damage, and possible loss of vision.

Although ingestion is unlikely in the occupational setting, it can cause irritation of the mouth, sore throat, coughing, salivation, nausea, and vomiting.

☠ *Acute Health Effects*

The following acute (short-term) health effects may occur immediately or shortly after exposure to methyl *n*-amyl ketone:

Skin: Irritation, dermatitis, and possible localized paresthesia.

Eye: Irritation with pain and inflammation that can lead to corneal damage and possible loss of vision.

Lung: Irritation causing coughing and/or shortness of breath. Higher exposures can cause dizziness, headache, and, possibly, coma and death.

CNS: A mild narcotic compound. It is not, however, considered neurotoxic. Inhalation of high concentrations of the vapor may cause dizziness, lightheadedness, and possible loss of consciousness.

☘ *Chronic Health Effects*

The following chronic (long-term) health effects may occur at some time after exposure to methyl *n*-amyl ketone and can last for months or even years:

Cancer Hazards: According to information presented in the references, methyl *n*-amyl ketone has not been adequately tested for its ability to cause cancer in laboratory test animals.

Reproduction: There are no reports to support any claims of reproductive hazards in humans or animals.

Sensitivity: Studies with methyl *n*-amyl ketone have shown that long-term skin exposure may produce

dermatitis. However, unlike other ketones, methyl *n*-amyl ketone is not considered a sensitizer.

🔒 **Recommended Risk-Reduction Measures**

Personnel should avoid direct contact with methyl *n*-amyl ketone. Unless a less toxic chemical can be substituted for a hazardous substance, *engineering controls* are the most effective method of reducing exposures. The best protection is to enclose operations and/or provide local exhaust ventilation at the site of chemical release. While not always operationally feasible, isolating operations can also reduce exposure. Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with methyl *n*-amyl ketone. For exposures to the PEL (100 ppm), use a NIOSH-approved, full facepiece organic vapor respirator. For higher or prolonged exposures, or when exposure levels are unknown (as in an emergency) a self-contained breathing apparatus (SCBA) with full facepiece operated in pressure demand mode, or a supplied-air respirator operated in continuous flow mode are the recommended respiratory protection methods of choice. If a full facepiece is not available, then chemical goggles should be worn to protect the eyes. Whenever a chemical splash hazard exists, a face shield and a rubber apron should be worn. To prevent hand and skin exposures, butyl rubber gloves should be used. Glove manufacturers should be contacted and permeation studies obtained *before* final glove selections are made.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with methyl *n*-amyl ketone.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where methyl *n*-amyl ketone is used or stored.

If symptoms develop or overexposure is suspected, the following medical tests may be helpful:

- ☑ Skin testing by a qualified allergist with special testing and careful evaluation of exposure history (may help diagnose allergy).
- ☑ Neurological evaluation of the central nervous system.

Other methods to reduce exposure include:

- ☑ Where possible, enclose operations and use local exhaust ventilation at the site of chemical release.

Explosion-proof design is recommended. If local exhaust ventilation or enclosure is not used, respiratory protection should be mandatory.

- ☑ Always ensure that proper protective clothing is worn when using chemical substances.
- ☑ Wash thoroughly immediately after exposure to methyl *n*-amyl ketone and at the end of the work shift or before eating, drinking, or smoking. Never wear clothes contaminated with methyl *n*-amyl ketone home. Family members can be exposed.
- ☑ Hazard warning information should be posted in the work area. As part of an *on-going* education and training program, all information on the health and safety hazards of methyl *n*-amyl ketone should be communicated to all exposed workers.

RISK ASSESSMENT: ENVIRONMENT

General Assessment

The environment is at risk of exposure during transportation, storage, disposal, or destruction of methyl *n*-amyl ketone. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance. Accidental spills, large or small, can result in fire, explosion, and possible contamination of the surrounding environmental mediums (water, soil, and air).

Methyl *n*-amyl ketone is considered a Class II combustible liquid (per OSHA 29 CFR 1910.106). It can react with strong oxidizers and acids to cause a serious fire and explosion hazard. When involved in a fire, it can release acrid and irritating oxides of carbon. A boiling liquid expanding vapor explosion (BLEVE) is also a possibility. These characteristics require special consideration during any emergency involving a leak or spill of methyl *n*-amyl ketone.

The proper disposal/destruction method for methyl *n*-amyl ketone is to burn it in a chemical incinerator (with molten salt treatment) equipped with an afterburner and air scrubber.

Methyl *n*-amyl ketone can enter the environment through manufacturing, unchecked discharge into effluents from industrial or municipal waste treatment plants, and through spills.

☠ **Acute Ecological Effects**

Acute (short-term) toxic effects may include the death of animals, birds, or fish, and death or low growth rate in plants. Acute effects are seen 2 to 4 days after ani-

imals or plants are exposed to methyl *n*-amyl ketone. This chemical has a slight acute toxicity to aquatic life. No data are available on the short-term effects of methyl *n*-amyl ketone on plants, birds, or land animals.

☪ *Chronic Ecological Effects*

Chronic (long-term) toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals. Methyl *n*-amyl ketone has slight chronic toxicity in aquatic life. No data are available to evaluate the long-term effects of methyl *n*-amyl ketone to plants, birds, or land animals.

💧 *Water Solubility*

Methyl *n*-amyl ketone is nearly insoluble in water. Concentrations of less than 1 milligram may mix with a liter of water.

🕒 *Persistence in the Environment*

Methyl *n*-amyl ketone is moderately persistent in water, with a half-life of between 20 to 200 days. The half-life of a pollutant is the amount of time it takes for one half of the chemical to be degraded.

🌊 *Bioaccumulation in Aquatic Organisms*

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans.

The concentration of methyl *n*-amyl ketone found in fish tissues is expected to be about the same as the average concentration of methyl *n*-amyl ketone in water from which the fish was taken.

🚫 *Recommended Risk-Reduction Measures*

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in a leak or spill to the environment. The correct use of DOT labeling (per the MSDS) on all containers, trucks, and rail cars will enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of methyl *n*-amyl ketone should be segregated from incompatible chemicals to minimize the risk of cross-contamination or contact. Buildings

designated for storage should be equipped with appropriate fire protection systems (alarms, sprinklers, emergency lighting, portable extinguishers).

If a spill or leak to the environment has occurred, fire department, emergency response, and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those trained in proper spill containment procedures. Contaminated soils should be removed for incineration and replaced with clean soil. If methyl *n*-amyl ketone should contact the water table, aquifer, or navigable waterway, time is of the essence. It is practically insoluble in water and, therefore, near total containment and remediation may be possible. When such spills occur, the local and/or state emergency response authorities may require notification. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of methyl *n*-amyl ketone.

If methyl *n*-amyl ketone is spilled or leaked, the following specific steps are recommended:

- ☑ Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened for normal work.
- ☑ Remove all ignition sources.
- ☑ Ventilate area of spill or leak.
- ☑ Absorb liquids in vermiculite, dry sand, earth, or a similar material and deposit in sealed containers for disposal.
- ☑ Keep methyl *n*-amyl ketone out of a confined space, such as a sewer, because of the possibility of explosion (unless the sewer is designed to prevent the buildup of explosive concentrations).
- ☑ It may be necessary to dispose of methyl *n*-amyl ketone as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving methyl *n*-amyl ketone can present a significant threat to business operations. The loss or damage of equipment or facilities can significantly affect fiscal viability. Lawsuits that may result from personnel injury, public exposures, and/or environmental contamination will also require a serious expenditure of resources. Media attention sur-

Risk Management for Hazardous Chemicals

rounding an injury, illness, or environmental damage can also result in a loss of profits and loss of current as well as future business prospects.

🕒 Recommended Risk-Reduction Measures

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures dealing with safety or emergency response. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

| Stable X | Unstable | Incompatibility (<i>materials to avoid</i>) Strong oxidizers (chlorine, bromine, fluorine), chemically active metals (potassium, aluminum, zinc, and magnesium). Attacks aluminum to form aluminum trimethyl which is spontaneously flammable. | | |
| Hazardous Polymerization | | Conditions to Avoid Hazardous polymerization of methyl bromide has not been reported to occur under normal conditions of temperature and pressure. The liquid attacks some plastics, rubber, and coatings. | | |
| May Occur | Will Not Occur X | Hazardous Decomposition or By-products Poisonous gases and acrid fumes are produced in fire, including carbon dioxide, carbon monoxide, hydrogen bromide, and toxic oxides of bromine. | | |
| SECTION VI - HEALTH HAZARD DATA | | | | |
| Primary Route(s) of Entry: | Inhalation? X | Absorption (skin/eye)? X | Ingestion? | |
| Health Hazards INHALATION: Poisonous. Symptoms of headache, nausea, dizziness, vomiting, blurred vision, slurred speech, convulsions, lung irritation with congestion, coughing, chest pain, shortness of breath, loss of consciousness, and death. Lung effects may be delayed. Can cause kidney damage. A neurotoxin causing muscle weakness and pain, behavioral changes. ABSORPTION: The liquid or gas can pass through intact skin to cause CNS effects. Liquid causes burns and blisters due to intense cold (frostbite) with subsequent destruction of tissues. INGESTION: Unspecified gastrointestinal effects. An unlikely exposure route, but still possible. | | | | |
| Carcinogenicity Suspected Human Suspected Animal | NTP Listed? No | IARC Cancer Review Group? Group 3 | OSHA Regulated? 29 CFR 1910.1000 Table Z-1 | Target Organs? Eyes, skin, respiratory sys., Liver, kidney, CNS, PNS. |
| Medical Conditions Generally Aggravated by Exposure Liver, kidney, heart, and respiratory problems may be aggravated by exposure. | | | | |
| Emergency and First-aid Procedures Eye contact: Do not allow victim to keep eyes tightly shut. Flush immediately with warm (tepid) water for 15 minutes (minimum); seek medical attention. Skin contact: Remove all contaminated clothing, including shoes. Immediately wash area with flooding warm (tepid) water. Do NOT rub area or use air-blown heat in an attempt to warm skin. Seek medical attention immediately. For inhalation: Remove the person from exposure. Provide respiratory assistance and CPR. Transfer to medical facility. Observe for 24-48 hours for lung effects. If swallowed: Unlikely exposure route. | | | | |
| SECTION VII - PRECAUTIONS FOR SAFE HANDLING AND USE | | | | |
| Steps to be Taken in Case Material is Released or Spilled Remove all ignition sources, wear SCBA respiratory protection. Restrict those not wearing protective equipment and who are not involved in cleanup from entering area. Stop leak if it can be done without risk. Provide explosion-proof ventilation. Absorb with-vermiculite and deposit in sealed containers. | | | | |
| Preferred Waste Disposal Method Mix with combustible solvent; burn in chemical incinerator equipped with an afterburner and scrubber. | | | | |
| Precautions to be Taken in Handling and Storage Store in tightly closed containers in cool, well-ventilated location. Keep away from sources of heat. | | | | |
| Other Precautions and Warnings Sources of ignition such as open flame or smoking, are prohibited where methyl bromide is used or stored. Metal containers should be bonded and grounded. Empty containers contain residue; handle with care. | | | | |
| SECTION VIII - CONTROL MEASURES AND PERSONAL PROTECTIVE EQUIPMENT | | | | |
| Respiratory Protection (<i>specify type</i>) Use an MSHA/NIOSH-approved air purifying respirator (cartridge type) or use a supplied-air respirator or a self-contained breathing apparatus (SCBA) with full facepiece operated in positive pressure mode. | | | | |
| Ventilation Local exhaust (preferred) at site of chemical work or general ventilation. | | | | |
| Protective Gloves Impervious Gloves | Eye Protection Chemical Goggles or Face Mask | Other Protective Clothing Protective Apron if Splash is Likely | | |
| Work/Hygiene Practices Always wash hands thoroughly after using chemical; never bring food, drink, or smoking materials into vicinity of chemicals. | | | | |

METHYL BROMIDECH₃Br

CAS: 74-83-9

**IDENTIFICATION AND TYPICAL USES**

Methyl bromide is a colorless gas with a sweet, chloroform-like odor at high concentrations. It can also exist as a liquid below 38°F (3.6°C) and is usually shipped as a liquefied compressed gas. It is used as a fumigant for pest control, for degreasing wool, and as a methylating agent. It has also been used as a refrigerant and in fire extinguishers, but these uses have been restrained or curtailed due to risks to human health and the environment posed by methyl bromide.

RISK ASSESSMENT: HEALTH**General Assessment**

Methyl bromide is a human poison by *inhalation*. Both the gas and the liquid have been known to pass through intact skin (dermal *absorption*) to cause toxic system effects with particular action on the central nervous system (CNS). Skin contact can also cause localized damage to tissues due to the extreme cold temperatures of the compressed or liquefied gas. Methyl bromide is a suspected animal carcinogen. Its human carcinogenic properties should also be considered suspect until further studies are performed. Human mutation data have been reported. Physiologically, it is a neurotoxin and is also thought to pose risk of injury or damage to the lungs, liver, and kidney. The primary human response to methyl bromide is depression of the central nervous system (CNS).

Inhalation causes irritation of the lungs, marked congestion and symptoms CNS depression. These can include drowsiness, slurred speech, lack of coordination, and possible loss of consciousness. There may also be headache, nausea, vomiting, anorexia, ataxia, numbness in the legs and arms, convulsions, and death. Irritation to the eyes and respiratory system is

also known to occur on inhalation. In fact, pulmonary edema (fluid buildup in the lungs) has been reported. This is a medical emergency that can be fatal. Symptoms of congestion, difficulty breathing, cough with phlegm, and chest pain may be delayed for up to 48 hours following exposure. This may create a false sense of security with regard to health risk.

Skin contact may cause localized burning and frostbite at site of contact with irritation and possible tissue destruction. Eye contact can result in severe irritation and/or damage to the cornea, with redness and swelling. Damage can be serious if not immediately flushed from eye surface. Oral administration of the liquid to test animals caused gastrointestinal tumors.

☠ Acute Health Effects

The following acute (short-term) health effects may occur immediately or shortly after exposure to methyl bromide:

- Skin:** Irritation and burning (frostbite) with potential for redness, pain, and inflammation.
- Eye:** Severe irritation, burning, pain, and permanent damage possible.
- Lung:** Nose, throat, and respiratory tract irritation causing difficulty in breathing, congestion, chest pains, possible pulmonary edema (fluid in lungs) on high exposure.
- CNS:** Narcosis, headaches, lightheadedness, dizziness, vertigo, coma, and death.

☠ Chronic Health Effects

The following chronic (long-term) health effects may occur at some time after exposure to methyl bromide and can last for months or even years:

Cancer Hazards: According to information presented in the references, exposure to methyl bromide may cause cancer in test animals. Human data are lacking but human carcinogenicity may be suspect. More research is required since the data in the references are inconclusive and conflicting in this regard.

Reproductive Hazard: According to information presented in the references, methyl bromide has not been adequately tested for its ability to cause adverse reproductive effects in test animals.

Other Chronic Effects: Long-term exposure may lead to CNS damage with speech difficulties, ataxia, mental confusion, and hallucinations. Skin damage may consist of chronic acneform eruptions. Liver and kidney damage may also occur. Extremely irritating substances have been known to damage lung tissues. It is not known whether exposure to methyl bromide will have this effect on humans.

🕒 Recommended Risk-Reduction Measures

Personnel should avoid direct contact with methyl bromide. Occupational poisoning occurs most commonly by inhalation or skin absorption. If a less toxic material or compound cannot be substituted for methyl bromide, then *engineering controls* are the most effective method of reducing exposures. The best protection is to enclose operations and/or provide local exhaust ventilation at the site of methyl bromide release. While not always operationally feasible, isolating operations can also reduce exposure. Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around methyl bromide. Caution should be exercised when selecting respiratory protection since it is not known if exposure to methyl bromide will cause cancer in humans. For exposure over the PEL (20 ppm), an MSHA/NIOSH-approved air-purifying respiratory with organic vapor cartridge(s) will suffice. For exposures to higher concentrations, or when the concentration is unknown (as in an emergency), use a supplied-air respirator with full facepiece and mask operated in positive pressure mode or a self-contained breathing apparatus (SCBA) with full facepiece operated in pressure demand. If a full facepiece is not available, then chemical goggles should be worn to protect the eyes. A face shield should also be considered. To prevent hand and skin exposures, impervious thermal protective gloves should be worn. Glove manufacturers should be con-

tacted and permeation studies obtained *before* final glove selections have been made.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with methyl bromide.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where methyl bromide is used or stored.

If symptoms develop or overexposure is suspected, the following recommended medical tests should be considered:

- Liver and kidney function tests.
- Lung function tests.
- Consider chest X-ray following acute overexposure (may be negative if taken immediately after exposure due to delayed onset of pulmonary edema).

Any evaluation should include a careful history of past and present symptoms with an examination. Medical tests that simply look for existing damage are not a substitute for controlling exposures. Also, since smoking causes heart disease, emphysema, and other respiratory problems, smokers exposed to methyl bromide may experience symptoms quicker and more pronounced than non-smokers under the same conditions of exposure. Prudent risk management requires careful consideration of *all* possible factors that may be causing the appearance of exposures symptoms in the work place.

Other methods to reduce exposure include:

- Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not used, respiratory protection should be mandatory.
- Always ensure that proper protective clothing is worn when using chemical substances.
- Wash thoroughly immediately after exposure to methyl bromide and at the end of the work shift or before eating, drinking, or smoking.
- Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of methyl bro-

mide should be communicated to all exposed workers.

- ☑ Eye wash stations should be provided in the immediate work area for emergency use. If there is a possibility of skin exposure to methyl bromide, emergency shower facilities should be provided.
- ☑ Workers whose clothing has been contaminated by methyl bromide should change into clean clothes before leaving work. Contaminated work clothing should be laundered only by individuals who have been informed of the hazards of methyl bromide.

RISK ASSESSMENT: ENVIRONMENT

General Assessment

The environment is at risk of exposure during transportation, storage, disposal, or destruction of methyl bromide. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance. Accidental spills, large or small, can result in contamination of the surrounding environmental mediums (water, soil, and air).

Methyl bromide is a moderately flammable gas. It is a dangerous fire hazard and moderate explosion hazard when exposed to heat or flame. Although it is considered a flammable gas, it does not easily ignite. It is incompatible with strong oxidizers, such as chlorine, fluorine, and bromine, and many chemically-active metals, such as sodium, potassium, calcium, powdered aluminum, zinc, and magnesium. It attacks aluminum to form aluminum triethyl which is spontaneously flammable. Caution is always required in handling, storage, transportation, and disposal of methyl bromide. Emergency responders should be made aware of the presence of methyl bromide at any emergency response situation.

Methyl bromide can enter the environment from industrial effluents and from spills.

☠ *Acute Ecological Effects*

Acute (short-term) toxic effects may include the death of animals, birds, or fish and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to methyl bromide. Methyl bromide has high acute toxicity to aquatic life. It has caused injury to various agricultural crops. Insufficient data are available to evaluate the short-term effects of methyl bromide on birds or land animals.

☠ *Chronic Ecological Effects*

Chronic (long-term) toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals. Methyl bromide has high chronic toxicity to aquatic life. Insufficient data are available to evaluate or predict the long-term effects of methyl bromide to plants, birds, or terrestrial animals.

💧 *Water Solubility*

Methyl bromide is only slightly soluble in water. Concentrations between 1 and 100 milligrams will mix with a liter of water.

⌚ *Persistence in the Environment*

Methyl bromide is slightly persistent in water, with a half-life between 2 and 20 days. The half-life of a pollutant is the amount of time it takes for one half of the chemical to be degraded.

🐟 *Bioaccumulation in Aquatic Organisms*

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans.

The concentration of methyl bromide found in fish tissues is expected to be about the same as the average concentration of methyl bromide in the water from which the fish was taken.

🛡️ *Recommended Risk-Reduction Measures*

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in a leak or spill of methyl bromide into the environment. Labels on all containers, trucks, and rail cars must meet DOT requirements and accurately reflect their contents to enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of methyl bromide should be segregated from other chemicals and materials to minimize the risk of cross-contamination.

If a spill or leak to the environment has occurred, fire department, emergency response and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those

trained in proper spill containment procedures. Contaminated soils should be removed for incineration and replaced with clean soil. If methyl bromide should contact the water table, aquifer, or navigable waterway, time is of the essence. It is slightly soluble and total remediation may not be possible. The local and/or state emergency response authorities must be notified. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of methyl bromide.

For disposal, methyl bromide may be mixed with a combustible solvent and burned in a chemical incinerator equipped with an afterburner and scrubber.

If methyl bromide is spilled or leaked, the following specific steps are recommended:

- Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete. Use non-sparking tools.
- Stop flow of gas. Use water to knock down vapors and to protect response crews attempting to shut off gas leak. If leak is from a cylinder and it cannot be stopped, remove to a safe area outdoors, if possible, and allow to vent until empty. Absorb any liquids in vermiculite, sand, earth, or similar material and deposit in sealed drum.
- Ventilate area of spill or leak and remove all ignition sources.
- It may be necessary to dispose of methyl bromide as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving methyl bromide can present a serious threat to business operations. The loss or damage of equipment or facilities can significantly affect fiscal viability. Lawsuits that may result from personnel illness, injury/death, public exposures, and/or environmental contamination will require a serious expenditure of resources.

Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business. Always remember that anytime terms such as "cancer" or "carcinogen" are used, public emotion, hysteria, and ignorance can run equally high. This must be carefully considered whenever developing or implementing a public relations policy.

Recommended Risk-Reduction Measures

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures for responding to chemical incidents. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

SECTION I - GENERAL INFORMATION

| | | |
|---|--|---------------------------------|
| Characterization Halogenated Hydrocarbon | RCRA Number U045 | EPA Class Toxic Waste |
| DOT Proper Shipping Name Methyl chloride | Chemical Abstract Service (CAS) Number 74-87-3 | |
| DOT Hazard Class and Label Requirements Flammable Gas | DOT Emergency Guide Code 18 | |
| DOT Identification Number UN 1063 | Molecular Formula CH₃Cl | |

Synonyms

Chloromethane; monochloromethane; methylene dichloride.

SECTION II - HAZARDOUS INGREDIENTS AND IDENTITY INFORMATION

| Hazardous Components (specific identity) | OSHA Exposure Criteria | NIOSH Exposure Criteria | Immediately Dangerous to Life and Health (IDLH) | ACGIH Exposure Criteria |
|--|---|--|---|--|
| Methyl chloride (derivation: By chlorination of methyl chloride and subsequent distillation). 1 ppm = 2.10 mg/m³ | PEL: 100 ppm 210 mg/m³ STEL: 200 ppm 420 mg/m³ | REL: Reduce to Lowest Level Possible Cancer Agent | 2000 ppm | TLV: 50 ppm 105 mg/m³ STEL: 100 ppm 210 mg/m³ |

SECTION III - PHYSICAL AND CHEMICAL CHARACTERISTICS

| | |
|---|---|
| Boiling Point -12°F (-24°C) | Specific Gravity (H ₂ O = 1) 0.997 |
| Vapor Pressure (atmospheres) 5.0 at 69°F (20°C) | Molecular Weight (atomic weight) 50.5 |
| Vapor Density (Air = 1) 1.78 | Freezing Point -144°F (-97°C) |

Solubility

Slightly soluble in water (0.5%). Soluble in alcohol, ether, chloroform, and glacial acetic acid.

Appearance and Odor

Colorless gas, with a faint, sweet ether-like odor that is not noticeable at dangerous levels. Normally shipped as a liquefied compressed gas. Odor Threshold = 10 ppm.

SECTION IV - FIRE AND EXPLOSION HAZARD DATA

| | |
|---|---|
| Flash Point (method used) <32°F (<0°C) closed cup | Explosive Limits in Air % by Volume LEL: 8.1% UEL: 17% |
| NFPA Classification Flammable Gas | Autoignition Temperature 1170°F (632°C) |

Extinguishing Media

Stop flow of gas first, if possible. Use dry chemical, carbon dioxide, water spray, or foam.

Special Fire Fighting Procedures

Poisonous gases are produced in fire. Wear self-contained breathing apparatus (SCBA) and full protective gear. Move containers from fire if it can be done without risk. Cool sides of fire-exposed containers with water until long after fire is out. Reacts with water to form hydrochloric acid.

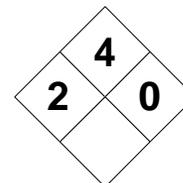

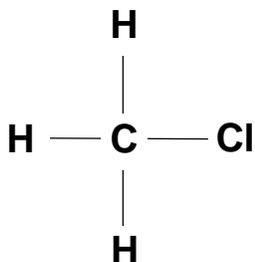

Unusual Fire and Explosion Hazards

Dangerous fire and explosion hazard. Containers may explode in fire. Its vapors are heavier than air and can travel for great distances to an ignition source to flashback and cause fire or explosion.

| SECTION V - REACTIVITY DATA | | | | |
|---|----------------------------|---|-----------------------------------|--|
| Stability | | Conditions to Avoid Methyl chloride is normally stable. Avoid heat, flame, other sources of ignition, and contact with incompatible materials and chemicals. | | |

| SECTION VI - HEALTH HAZARD DATA | | | | |
| Primary Route(s) of Entry: | | Inhalation? X | Absorption (skin/eye)? | Ingestion? |
| Health Hazards INHALATION: Causes depression of the central nervous system (CNS) with stupor, eye irritation, incoordination, abdominal cramps, anesthetic effects, unconsciousness, and cardiac arrest. May damage liver and kidneys. Vapors may cause irritation to the eyes, nose, and throat. EYES & SKIN: Irritation, redness and pain from frostbite to the skin. Eye contact may result in severe irritation and possible permanent damage due to frostbite. INGESTION: Unspecified gastrointestinal effects. An unlikely exposure route, but still possible. | | | | |
| Carcinogenicity | NTP Listed? | IARC Cancer Review Group? | OSHA Regulated? | Target Organs? |
| Unknown Human Questioned Animal | No | Group 3 | 29 CFR 1910.1000 Table Z-1 | Eyes, skin, respiratory sys., liver, kidney, CVS, CNS. |
| Medical Conditions Generally Aggravated by Exposure None reported. However, liver, kidney, heart, and respiratory problems may be aggravated by exposure. | | | | |
| Emergency and First-aid Procedures Eye contact: Do not allow victim to keep eyes tightly shut. Flush immediately with tepid water (104°F), for 15 minutes (minimum); seek medical attention. Skin contact: Remove all contaminated clothing, including shoes. Immediately wash area with flooding amounts of warm water (104°F). Do NOT rub affected area or use dry heat. Seek medical attention immediately. For inhalation: Remove the person from exposure. Provide respiratory assistance and CPR. Transfer to medical facility. If swallowed: Seek medical attention immediately. Give conscious and alert person 1-2 glasses of water and induce vomiting. Never give an unconscious or convulsing person anything by mouth. | | | | |
| SECTION VII - PRECAUTIONS FOR SAFE HANDLING AND USE | | | | |
| Steps to be Taken in Case Material is Released or Spilled Remove all ignition sources; wear SCBA respiratory protection. Restrict those not wearing protective equipment and who are not involved in cleanup from entering area. Stop leak if it can be done without risk. Spilled liquids are likely to evaporate quickly. Absorb with vermiculite and place in sealed container. | | | | |
| Preferred Waste Disposal Method Burn in chemical incinerator equipped with an afterburner and scrubber. | | | | |
| Precautions to be Taken in Handling and Storage Store in tightly closed containers in cool, well-ventilated location. Keep away from sources of heat. | | | | |
| Other Precautions and Warnings Sources of ignition such as open flame or smoking, are prohibited where methyl chloride is used. Metal containers should be bonded and grounded. Empty cylinders contain residue; handle with care. | | | | |
| SECTION VIII - CONTROL MEASURES AND PERSONAL PROTECTIVE EQUIPMENT | | | | |
| Respiratory Protection (<i>specify type</i>) Use an MSHA/NIOSH-approved air purifying respirator (cartridge type) or use a supplied-air respirator or a self-contained breathing apparatus (SCBA) with full facepiece operated in positive pressure mode. | | | | |
| Ventilation Local exhaust (preferred) at site of chemical work or general ventilation. | | | | |
| Protective Gloves Viton, Nitrile, or Butyl Rubber Gloves | | Eye Protection Chemical Goggles or Face Mask | | Other Protective Clothing Protective Apron if Splash is Likely |
| Work/Hygiene Practices Always wash hands thoroughly after using chemical; never bring food, drink, or smoking materials into vicinity of chemicals. | | | | |

METHYL CHLORIDECH₃Cl

CAS: 74-87-3

**IDENTIFICATION AND TYPICAL USES**

Methyl chloride is a colorless gas with a faint, sweet, ether-like odor. It is used as a catalyst in low-temperature polymerization (butyl rubber), in the manufacture of tetramethyl lead, in silicones, as a refrigerant, as a fluid for thermometric and thermostatic equipment, as a methylating agent in organic synthesis (such as that of methylcellulose), as an extractant and low-temperature solvent, an herbicide, and a topical anesthetic.

RISK ASSESSMENT: HEALTH**General Assessment**

Methyl chloride is mildly toxic by *inhalation*. Although it is normally a gas at room temperature, it is normally shipped as a compressed liquid at temperatures below -144°F (-97°C) and, therefore, methyl chloride can cause serious damage on skin contact (localized tissue damage due to the extremely cold temperatures of the compressed or liquefied gas).

Inhalation is irritating to the eyes, nose, and mucosa of the respiratory tract. High concentrations of methyl chloride causes depression of the central nervous system and cardiac arrhythmia. Symptoms include dizziness, lightheadedness, headache, stupor, drunkenness and inebriation, loss of coordination, abdominal cramps, blurred vision, delayed pulmonary edema (fluid buildup in the lungs), unconsciousness, and possible cardiac arrest, liver, and kidney damage. Symptoms of pulmonary edema can be delayed up to 48 hours, thereby creating a false sense of security with regard to health exposure risk. It should also be noted that such symptoms as inebriation and drunkenness can also lead to accidents. Personnel may injure

themselves or others, or damage equipment and property, as a result of the intoxicating effects of exposure.

Skin contact can produce allergic eczema and severe tissue damage due to frostbite. Eye contact will also cause serious injury to tissues as a result of the extremely cold temperatures of both the liquid and the compressed gas.

☠ Acute Health Effects

The following acute (short-term) health effects may occur immediately or shortly after exposure to methyl chloride:

- Skin:** Irritation with potential for redness, pain, frostbite, and tissue damage. Possible allergic eczema can develop.
- Eye:** Severe irritation, burning (frostbite), pain, and smarting of the conjunctiva. Permanent damage to visual acuity is possible.
- Lung:** Nose, throat, and respiratory tract irritation. Absorption through the lungs is quick.
- CNS:** Headaches, lightheadedness, dizziness, inebriation, loss of coordination, stupor, and drunkenness. Death can occur due to cardiac arrhythmia and possible cardiac arrest.

☘ Chronic Health Effects

The following chronic (long-term) health effects may occur at some time after exposure to methyl chloride and can last for months or even years:

Cancer Hazards: The National Institute for Occupational Safety and Health (NIOSH) considers methyl chloride to be a carcinogen and the International Agency for Research on Cancer (IARC) has conducted studies yielding insufficient evidence that methyl

chloride is a tumorigenic agent. However, no carcinogenic designations have been assigned to this chemical. Further study and confirmation is required. It is recommended that users proceed with due caution until more is known about the carcinogenic properties of methyl chloride.

Reproductive Hazard: According to information presented in the references, methyl chloride may cause damage to the testes and other reproductive or possible teratogenic effects.

Other Chronic Effects: Repeated exposure to low concentrations may cause damage to central nervous system and, less frequently, to the liver, kidneys, bone marrow, and cardiovascular system. Hemorrhages into the lungs, intestinal tract, and dura have been reported.

🕒 **Recommended Risk-Reduction Measures**

Personnel should avoid direct contact with methyl chloride. Occupational poisoning occurs most commonly by inhalation. If a less toxic material or compound cannot be substituted for methyl chloride, then *engineering controls* are the most effective method of reducing exposures. The best protection is to enclose operations and/or provide local exhaust ventilation at the site of methyl chloride release. While not always operationally feasible, isolating operations can also reduce exposure. Using respiratory protection is less effective than the controls mentioned above, but is still required whenever working with or around methyl chloride. Caution should be exercised when selecting respiratory protection since it is not known if exposure to methyl chloride will cause cancer in humans. For exposure over the PEL (100 ppm), an MSHA/NIOSH-approved air-purifying respiratory with organic vapor cartridge(s) may suffice. For exposures to higher concentrations, or when the concentration is unknown (as in an emergency), use a supplied-air respirator with full facepiece and mask operated in positive pressure mode or a self-contained breathing apparatus (SCBA) with full facepiece operated in pressure demand. If a full facepiece is not available, then chemical goggles should be worn to protect the eyes. A face shield should also be considered. To prevent hand and skin exposures, nitrile, Viton, or butyl rubber gloves should be used. Glove manufacturers should be contacted and permeation studies obtained *before* selecting gloves.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which

specify the methods and techniques that will be practiced whenever personnel are to work with methyl chloride.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where methyl chloride is used or stored.

If symptoms develop or overexposure is suspected, the following recommended medical tests should be considered:

- Lung function tests.
- Liver and kidney function tests.
- Consider chest X-ray following acute overexposure (may be negative if taken immediately after exposure due to delayed onset of pulmonary edema).
- Interview for nervous system and brain effects, including recent changes in memory, mood (irritability, withdrawal), and concentration. Look for headaches, malaise, and altered sleeping patterns. Cerebellar, autonomic, and peripheral nervous system evaluation should be considered. Positive or borderline cases should be referred for further neuropsychological testing.
- Complete blood count (CBC).

Any evaluation should include a careful history of past and present symptoms with an examination. Medical tests that simply look for existing damage are not a substitute for controlling exposures. Also, since smoking causes lung cancer, emphysema, heart disease, and other adverse health effects, smokers exposed to methyl chloride may experience symptoms more rapidly than non-smokers under the same conditions of exposure. Prudent risk management requires proper consideration of *all* factors which may be responsible for the appearance of exposure symptoms in the workplace.

Other methods to reduce exposure include:

- Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not used, respiratory protection should be mandatory.
- Always ensure that proper protective clothing is worn when using chemical substances.
- Wash thoroughly immediately after exposure to methyl chloride and at the end of the work shift or before eating, drinking, or smoking.

- ☑ Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of methyl chloride should be communicated to all exposed and potentially exposed workers.
- ☑ Eye wash stations should be provided in the immediate work area for emergency use. If there is a possibility of skin exposure to methyl chloride, emergency shower facilities should also be provided in the immediate area.
- ☑ Workers whose clothing has been contaminated by methyl chloride should change into clean clothes before leaving work. Contaminated work clothing should be laundered only by individuals who have been informed of the hazards of exposure to methyl chloride.
- ☑ Where possible, automatically transfer liquids containing methyl chloride from drums or other containers to process containers.

RISK ASSESSMENT: ENVIRONMENT

General Assessment

Although methyl chloride normally exists as a gas, it is usually shipped as a liquefied compressed gas. The environment is at risk of exposure during transportation, storage, disposal, or destruction of methyl chloride. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance. Accidental spills, large or small, can result in contamination of the surrounding environmental mediums (water, soil, and air).

Methyl chloride is very dangerous flammable gas. It is a serious fire hazard and moderate explosion hazard when exposed to heat or flame. It is incompatible with strong oxidizers, such as chlorine, fluorine, and bromine, and many chemically-active metals, such as sodium, potassium, calcium, powdered aluminum, zinc, and magnesium. Caution is always required in handling, storage, transportation, and disposal of methyl chloride. Emergency responders should be made aware of the presence of methyl chloride at any emergency response situation.

Methyl chloride can enter the environment from industrial discharges and from spills.

☠ *Acute Ecological Effects*

Acute (short-term) toxic effects may include the death of animals, birds, or fish and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to methyl chloride.

Methyl chloride has slight acute toxicity to aquatic life. Insufficient data are available to evaluate or predict the short-term effects of methyl chloride on plants, birds, or land animals.

☞ *Chronic Ecological Effects*

Chronic (long-term) toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals.

Methyl chloride has slight chronic toxicity to aquatic life. Insufficient data are available to evaluate or predict the long-term effects of methyl chloride to plants, birds, or terrestrial animals.

💧 *Water Solubility*

Methyl chloride is moderately soluble in water. Concentrations between 1 and 1000 milligrams will mix with a liter of water.

⌚ *Persistence in the Environment*

Methyl chloride is non-persistent in water, with a half-life of less than 2 days. The half-life of a pollutant is the amount of time it takes for one half of the chemical to be degraded. About 99.8% of methyl chloride will eventually end up in air; the remainder will end up in water.

🌊 *Bioaccumulation in Aquatic Organisms*

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans.

The concentration of methyl chloride found in fish tissues is expected to be about the same as the average concentration of methyl chloride in the water from which the fish was taken.

🛑 *Recommended Risk-Reduction Measures*

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in a leak or spill of methyl chloride into the environment. Labels on all containers, trucks, and rail cars must meet DOT

requirements and accurately reflect their contents to enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of methyl chloride should be segregated from other chemicals and materials to minimize the risk of cross-contamination.

If a spill or leak to the environment has occurred, fire department, emergency response and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those trained in proper spill containment procedures using non-sparking tools. Contaminated soils should be removed for incineration and replaced with clean soil. If methyl chloride should contact the water table, aquifer, or navigable waterway, time is of the essence. It is highly soluble and total remediation may not be possible. The local and/or state emergency response authorities must be notified. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of methyl chloride.

For disposal, methyl chloride may be burned in a chemical incinerator equipped with an afterburner and scrubber. It should be noted that complete destruction by incineration is difficult unless a direct gas feed to the incinerator is used. These are normally available in permit-approved facilities only. Complete combustion is necessary to prevent the formation of phosgene gas.

If methyl chloride is spilled or leaked, the following specific steps are recommended:

- Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete. Use only non-sparking tools.
- If source of leak is a cylinder, attempt to shut off leak if it can be done without risk. If not, try to move cylinder to a safe place (outdoors) and allow to vent. If fire occurs, use water spray to knock down vapors and direct away from personnel. Absorb liquids in vermiculite, sand, earth, or similar material and deposit in sealed drum.
- Ventilate area of spill or leak and remove all ignition sources.
- It may be necessary to dispose of methyl chloride as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving methyl chloride can present a serious threat to business operations. The loss or damage of equipment or facilities can significantly affect fiscal viability. Lawsuits that may result from personnel illness, injury/death, public exposures, and/or environmental contamination will require a serious expenditure of resources. Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business.

Recommended Risk-Reduction Measures

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures for responding to chemical incidents. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

METHYL CHLOROFORM

CAS: 71-55-6

**IDENTIFICATION AND TYPICAL USES**

Methyl chloroform is a colorless liquid with a sweet, chloroform-like odor. It is primarily an industrial cleaning solvent for metals and plastic molds. It is also used in pesticides, as a component in drain cleaners and inks, and in textile processing. It has also been used extensively as a substitute for carbon tetrachloride.

RISK ASSESSMENT: HEALTH**General Assessment**

Methyl chloroform is moderately toxic by *inhalation*. Although an unlikely exposure route, *ingestion* can also cause adverse systemic effects. While skin contact certainly causes localized, topical effects, the data on its ability to pass through intact skin (absorption) are conflicting and inconclusive. Methyl chloroform is an experimental teratogen and a known mutagen. There are insufficient data regarding its carcinogenic potential.

Inhalation is irritating to the eyes, nose, and mucosa of the respiratory tract. High concentrations of methyl chloroform vapors causes inflammation of the conjunctiva, depression of the central nervous system, and cardiac arrhythmia. Symptoms include dizziness, lightheadedness, headache, stupor, hallucinations, loss of coordination, abdominal cramps, irritability, equilibrium disturbances, aggressive behavior, hypermotility, unconsciousness, possible cardiac arrest, and liver and kidney damage. Ingestion can also cause these symptoms as well as nausea, vomiting, diarrhea, and gastrointestinal irritation. It is narcotic at high concentrations. It causes proarrhythmic activity which sensitizes the heart to epinephrine-induced arrhythmia. This can lead to cardiac arrest.

Skin contact result in the removal of the skin's natural, protective oily barrier (de-fatting) which can then lead to irritation, dryness, redness, cracking, and possible secondary infections. Eye contact will also cause serious irritation and inflammation of surrounding tissue and possible burning and stinging of the eye.

☠ Acute Health Effects

The following acute (short-term) health effects may occur immediately or shortly after exposure to methyl chloroform:

- Skin:** Irritation with potential for redness, pain, dryness, scaling, cracking, and infection. Dermatitis may occur in some individuals.
- Eye:** Severe irritation, burning, pain, and smarting of the conjunctiva. Permanent damage to visual acuity is possible.
- Lung:** Nose, throat, and respiratory tract irritation. High concentrations can cause severe irritation.
- CNS:** Headaches, lightheadedness, dizziness, hallucinations, loss of coordination, aggressive behavior, motor changes. Death can occur due to cardiac arrhythmia and possible cardiac arrest.

☘ Chronic Health Effects

The following chronic (long-term) health effects may occur at some time after exposure to methyl chloroform and can last for months or even years:

Cancer Hazards: According to information presented in the references, there is limited but insufficient evidence to conclude that exposure to methyl chloroform causes cancer in test animals. It is known to cause

mutations (genetic changes) and many scientists believe that such chemicals may pose a cancer risk in the long-term. More research is required before any determinations can be made regarding carcinogenicity.

Reproductive Hazard: According to information presented in the references, methyl chloroform may cause reproductive damage or possible teratogenic effects in test animals. Human teratogenicity is unknown.

Other Chronic Effects: High or repeated exposures may damage the liver and kidneys. Prolonged skin contact can cause thickening and cracking of the skin.

🔑 Recommended Risk-Reduction Measures

Personnel should avoid direct contact with methyl chloroform. The exact nature of toxic effects on human exposure is not clearly understood in the references. Occupational poisoning occurs most commonly by inhalation. If a less toxic material or compound cannot be substituted for methyl chloroform, then *engineering controls* are the most effective method of reducing exposures. The best protection is to enclose operations and/or provide local exhaust ventilation at the site of methyl chloroform release. While not always operationally feasible, isolating operations can also reduce exposure. Using respiratory protection is less effective than the controls mentioned above, but is still required whenever working with or around methyl chloroform. Caution should be exercised when selecting respiratory protection since it is not known if exposure to methyl chloroform will cause cancer in humans. For exposure over the PEL (350 ppm), an MSHA/NIOSH-approved air-purifying respiratory with organic vapor cartridge(s) may suffice. For exposures to higher concentrations, or when the concentration is unknown (as in an emergency), use a supplied-air respirator with full facepiece and mask operated in positive pressure mode or a self-contained breathing apparatus (SCBA) with full facepiece operated in pressure demand. If a full facepiece is not available, then chemical goggles should be worn to protect the eyes. A face shield should also be considered. To prevent hand and skin exposures, nitrile, Viton, or butyl rubber gloves should be used. Glove manufacturers should be contacted and permeation studies obtained *before* selecting gloves.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with methyl chloroform.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where methyl chloroform is used or stored.

If symptoms develop or overexposure is suspected, the following recommended medical tests should be considered:

- ☑ Liver and kidney function tests.
- ☑ Interview for nervous system depression and indications of recent mood changes or changes in behavior.

Any evaluation should include a careful history of past and present symptoms with an examination. Medical tests that simply look for existing damage are not a substitute for controlling exposures. Also, persons with heart disease may be at increased risk of irregular heartbeat from very high exposures to methyl chloroform. Proper risk management requires careful consideration of exposure potential during personnel selection and placement.

Other methods to reduce exposure include:

- ☑ Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not used, respiratory protection should be mandatory.
- ☑ Always ensure that proper protective clothing is worn when using chemical substances and that personnel are trained on its use and care.
- ☑ Wash thoroughly immediately after exposure to methyl chloroform and at the end of the work shift or before eating, drinking, or smoking.
- ☑ Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of methyl chloroform should be communicated to all exposed and potentially exposed workers.
- ☑ Eye wash stations should be provided in the immediate work area for emergency use. If there is a possibility of skin exposure to methyl chloroform, emergency shower facilities should also be provided in the immediate area.
- ☑ Workers whose clothing has been contaminated by methyl chloroform should change into clean clothes before leaving work. Contaminated work clothing should be laundered only by individuals who have been informed of the hazards of exposure to methyl chloroform.

- ☑ Where possible, automatically transfer liquids containing methyl chloroform from drums or other containers to process containers.

RISK ASSESSMENT: ENVIRONMENT

General Assessment

The environment is at risk of exposure during transportation, storage, disposal, or destruction of methyl chloroform. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance. Accidental spills, large or small, can result in contamination of the surrounding environmental mediums (water, soil, and air).

Methyl chloroform is considered a non-combustible liquid, although it may ignite with some degree of difficulty. Its vapors, however, can form flammable mixtures in air that can easily ignite, especially in confined areas. It is incompatible with strong oxidizers, such as chlorine, fluorine, and bromine, and many chemically-active metals, such as sodium, potassium, calcium, powdered aluminum, zinc, and magnesium. Caution is always required in handling, storage, transportation, and disposal of methyl chloroform. Emergency responders should be made aware of the presence of methyl chloroform at any emergency response situation.

Methyl chloroform can enter the environment from industrial and municipal waste treatment plant discharges and from spills.

☠ Acute Ecological Effects

Acute (short-term) toxic effects may include the death of animals, birds, or fish and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to methyl chloroform.

Methyl chloroform has moderate acute toxicity to aquatic life. Insufficient data are available to evaluate or predict the short-term effects of methyl chloroform on plants, birds, or land animals.

☪ Chronic Ecological Effects

Chronic (long-term) toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals.

Methyl chloroform has moderate chronic toxicity to aquatic life. Insufficient data are available to evaluate or predict the long-term effects of methyl chloroform to plants, birds, or terrestrial animals.

💧 Water Solubility

Methyl chloroform is moderately soluble in the aquatic environment. Concentrations between 1 and 1000 milligrams will mix with a liter of water.

⌚ Persistence in the Environment

Methyl chloroform is non-persistent in water, with a half-life of less than 2 days. The half-life of a pollutant is the amount of time it takes for one half of the chemical to be degraded. About 99.9% of methyl chloroform will eventually end up in air; the remainder will end up in water.

🌊 Bioaccumulation in Aquatic Organisms

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans.

The concentration of methyl chloroform found in fish tissues is expected to be somewhat higher than the average concentration of methyl chloroform in the water from which the fish was taken.

🛡 Recommended Risk-Reduction Measures

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in a leak or spill of methyl chloroform into the environment. Labels on all containers, trucks, and rail cars must meet DOT requirements and accurately reflect their contents to enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of methyl chloroform should be segregated from other chemicals and materials to minimize the risk of cross-contamination.

If a spill or leak to the environment has occurred, fire department, emergency response and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those trained in proper spill containment procedures using non-sparking tools. Contaminated soils should be removed for incineration and replaced with clean soil. Should methyl chloroform contact the water table, aquifer, or navigable waterway, time is of the essence. It is moderately soluble and total remediation may not be possible. The local and/or state emergency response authorities must be notified. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations in-

Risk Management for Hazardous Chemicals

volving the use, transportation, storage, or disposal of methyl chloroform.

For disposal, methyl chloroform may be mixed with a combustible solvent and burned in a chemical incinerator equipped with an afterburner and scrubber system. Complete combustion is necessary to prevent the formation of phosgene gas.

If methyl chloroform is spilled or leaked, the following specific steps are recommended:

- ☑ Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete. Use only non-sparking tools.
- ☑ If fire occurs, use water spray to knock down vapors and direct away from personnel. Absorb liquids in vermiculite, sand, earth, or similar material and deposit in sealed drum. Collect using non-sparking tools.
- ☑ Ventilate area of spill or leak and remove all ignition sources.
- ☑ It may be necessary to dispose of methyl chloroform as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving methyl chloroform can present a serious threat to business operations. The loss or damage of equipment or facilities can significantly affect fiscal viability. Lawsuits that may result from personnel illness, injury/death, public exposures, and/or environmental contamination will require a serious expenditure of resources. Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business. Always remember that anytime the terms "cancer" or "reproductive hazard" are used, public emotion, hysteria, and ignorance can run equally high. This must be carefully considered whenever developing or implementing public relations policies.

Recommended Risk-Reduction Measures

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures for responding to chemical incidents. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and

policies should be developed, approved, and implemented long before any need for such arises.

| SECTION VII - PRECAUTIONS FOR SAFE HANDLING AND USE | | | | |
| Steps to be Taken in Case Material is Released or Spilled Absorb spills in vermiculite, dry sand, earth, or similar material and deposit in sealed containers. Ventilate area of spill or leak. Restrict those not involved in cleanup from entering area. Remove all sources of ignition and stay up wind. Water spray may be used to knock down or reduce airborne vapor concentrations and to protect emergency response crews. | | | | |
| Preferred Waste Disposal Method No Citation. | | | | |
| Precautions to be Taken in Handling and Storage Store to avoid contact with incompatible materials in tightly closed containers in cool, well-ventilated area away from heat and flame. Use only non-sparking tools to open and close containers. | | | | |
| Other Precautions and Warnings Sources of ignition are prohibited where methylcyclohexane is used, handled, or stored. Heat may cause containers to build up pressure and explode. Bond and ground all containers during transfer. | | | | |
| SECTION VIII - CONTROL MEASURES AND PERSONAL PROTECTIVE EQUIPMENT | | | | |
| Respiratory Protection (specify type) For exposures above the PEL, use an MSHA/NIOSH-approved organic vapor respirator or a supplied-air respirator with full facepiece, hood, or helmet in continuous flow mode, or use a self-contained breathing apparatus (SCBA) operated in pressure demand or other positive pressure mode. | | | | |
| Ventilation Local exhaust or general mechanical systems recommended. | | | | |
| Protective Gloves Impervious Material | | Eye Protection Chemical Goggles or Face Mask | | Other Protective Clothing Protective Apron |
| Work/Hygiene Practices Always wash hands thoroughly after using chemical; never bring food, drink, or smoking materials into vicinity of chemicals. | | | | |

METHYLCYCLOHEXANEC₃C₆H₁₁

CAS: 108-87-2

**IDENTIFICATION AND TYPICAL USES**

Methylcyclohexane is a colorless liquid with a faint, benzene-like odor. It is used as a solvent for cellulose ethers and as an intermediate in organic synthesis.

RISK ASSESSMENT: HEALTH***General Assessment***

Methylcyclohexane is moderately toxic by *ingestion* and mildly toxic by *inhalation*. There are no reports of any carcinogenic, mutagenic, or teratogenic effects in humans or test animals.

Significant inhalation may cause irritation of the respiratory tract and depress the central nervous system. Symptoms include nausea, lightheadedness, drowsiness, dizziness, vomiting, and depression. At high concentrations, it is a narcotic and can lead to unconsciousness. It is of low chronic toxicity due to its efficient metabolism and excretion. It does *not* produce toxic changes to nerve cells and peripheral neuropathy normally associated with exposure to *n*-hexane. Vascular degenerative kidney lesions were reported in test animals.

Skin and eye contact may produce mild to moderate irritation on contact. There may be dermal thickening and ulceration of the skin surface. Eye contact may cause irritation and possible inflammation.

☠ *Acute Health Effects*

The following acute (short-term) health effects may occur immediately or shortly after exposure to methylcyclohexane:

Skin: Mild to moderate irritation.

Eye: Mild to moderate irritation.

Lung: High concentrations may irritate the lungs and nasal passages. Primary result of inhalation of methylcyclohexane is its action on the CNS.

CNS: A CNS depressant causing headache, dizziness, depression, excitement, dizziness, drowsiness, lightheadedness, changes in mood, and other narcotic effects up to and including loss of consciousness (at high concentrations).

☠* *Chronic Health Effects*

The following chronic (long-term) health effects may occur at some time after exposure to methylcyclohexane and can last for months or even years:

Cancer Hazards: According to information presented in the references, methylcyclohexane has not been adequately tested for its ability to cause cancer in animals.

Reproductive Hazard: According to information presented in the references, methylcyclohexane has not been tested for its ability to adversely affect reproduction.

Other Chronic Effects: Prolonged skin contact may cause drying, cracking, and chapping of the affected area. Repeated or long-term exposures to methylcyclohexane may affect the liver and kidneys.

🚫 *Recommended Risk-Reduction Measures*

Personnel should avoid direct contact with methylcyclohexane. The specific toxicity of this chemical is clearly understood in the references but it is believed to have the capability of causing significant health effects if improperly used or if overexposures occur. If a less toxic chemical cannot be substituted for a hazardous substance, then *engineering controls* are the most effective method of reducing exposures. The best protection is to enclose operations and/or provide local exhaust ventilation at the site of chemical release. While not always operationally feasible, isolating operations can also reduce exposure. Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around methylcyclohexane. For exposures above the PEL (500 ppm), an organic vapor respirator, a supplied-air respirator with full facepiece operated in continuous flow mode, or a self-contained breathing apparatus (SCBA) with full facepiece and pressure demand are the recommended respiratory protection methods of choice. If a full facepiece is not available, then chemical goggles should be worn to protect the eyes. Whenever a chemical splash hazard exists, a face shield and a rubber apron should be worn. To prevent hand and skin exposures, impervious gloves should be used. Glove manufacturers should be contacted and permeation studies obtained *before* final glove selections have been made.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with methylcyclohexane.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where methylcyclohexane is used or stored.

If symptoms develop or overexposure is suspected, the following tests are recommended:

- Kidney and liver function tests.

Any evaluation should include a careful history of past and present symptoms with an examination. Medical tests that simply look for existing damage are not a substitute for controlling exposures.

Other methods to reduce exposure include:

- Where possible, enclose operations and use local exhaust ventilation at the site of chemical release.

If local exhaust ventilation or enclosure is not used, respiratory protection should be mandatory.

- Always ensure that proper protective clothing is worn when using chemical substances and that personnel are trained on its proper use and care.
- Wash thoroughly immediately after exposure to methylcyclohexane and at the end of the work shift or before eating, drinking, or smoking.
- Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of methylcyclohexane should be communicated to all exposed and potentially exposed workers.
- Eye wash stations should be provided in the immediate work area for emergency use. If there is a possibility of skin exposure to methylcyclohexane, emergency shower facilities should also be provided in the work area.
- Personnel should never wear contaminated clothing home (family members can be exposed). Clothing should be laundered by personnel who have been trained on the hazards of methylcyclohexane.

RISK ASSESSMENT: ENVIRONMENT

General Assessment

The environment is at risk of exposure during transportation, storage, disposal, or destruction of methylcyclohexane. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance. Accidental spills, large or small, can result in fire, explosion, and possible contamination of the surrounding environmental mediums (water, soil, and air).

Methylcyclohexane is considered a Class 1B flammable liquid (per OSHA 29 CFR 1910.106). Its extremely low flash point and relatively low boiling point make this chemical a serious fire and explosion hazard concern. During tank or rail car fires, a boiling liquid expanding vapor explosion (BLEVE) is possible. The area should be evacuated when a rising sound is heard from a venting device or a discoloration of the tank ends becomes noticeable. These characteristics require extreme caution in handling, storage, transportation, and disposal. It is incompatible with common oxidizers and contact can cause fire or explosion. Therefore, special consideration is required during any emergency situation involving a

leak or spill of methylcyclohexane. Should methylcyclohexane ever come into contact with these incompatible substances during use, transportation, storage, or disposal, the formation of highly toxic and/or highly explosive commodities is extremely possible.

Methylcyclohexane may enter the environment through industrial discharges or spills.

☠ *Acute Ecological Effects*

Acute (short-term) toxic effects may include the death of animals, birds, or fish and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to methylcyclohexane.

Insufficient data are available to evaluate or predict the short-term effects of methylcyclohexane exposure to aquatic life, plants, birds, or land animals.

🕒 *Chronic Ecological Effects*

Chronic (long-term) toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals.

Insufficient data are available to evaluate or predict the long-term effects of methylcyclohexane to aquatic life, plants, birds, or land animals.

💧 *Water Solubility*

Methylcyclohexane is insoluble in water. Concentrations of less than 1 milligram will not mix with a liter of water.

🕒 *Persistence in the Environment*

Methylcyclohexane is non-persistent in water, with a half-life of less than 2 days. The half-life of a pollutant is the amount of time it takes for one half of the chemical to be degraded. Virtually 100% of methylcyclohexane will eventually end up in air.

🐟 *Bioaccumulation in Aquatic Organisms*

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans.

The concentration of methylcyclohexane found in fish tissue is expected to be about the same as the av-

erage concentration of methylcyclohexane in the water from which the fish was taken.

🛡️ *Recommended Risk-Reduction Measures*

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in a leak or spill to the environment. The correct use of DOT labeling (per the MSDS) on all containers, trucks, and rail cars will enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of methylcyclohexane should be segregated from incompatible chemicals to minimize the risk of cross-contamination or contact. Buildings designated for storage should be equipped with appropriate fire protection systems (alarms, sprinklers, emergency lighting, portable extinguishers).

If a spill or leak to the environment has occurred, fire department, emergency response and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those trained in proper spill containment procedures using non-sparking tools. Contaminated soils should be removed for incineration and replaced with clean soil. If methylcyclohexane should contact the water table, aquifer, or navigable waterway, the local and/or state emergency response authorities must be notified. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of methylcyclohexane. If methylcyclohexane is spilled or leaked, the following specific steps are recommended:

- Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened for normal work.
- Remove all ignition sources
- Ventilate area of leak or spill. Depending upon amount and location of spill, explosion-proof ventilation system may be necessary.
- Absorb liquids in vermiculite, dry sand, earth, or similar material and deposit in sealed containers.
- It may be necessary to dispose of methylcyclohexane as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving methylcyclohexane can present a significant threat to business operations. The loss or damage of equipment or facilities can significantly affect fiscal viability. Lawsuits that may result from personnel injury/death, public exposures, and/or environmental contamination will also require a serious expenditure of resources. Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business.

Recommended Risk-Reduction Measures

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures dealing with safety or emergency response. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

| SECTION VI - HEALTH HAZARD DATA | | | | |
| Primary Route(s) of Entry: | | Inhalation? X | Absorption (skin)? X | Ingestion? X |
| Health Hazards INHALATION: Can produce human systemic effects, including conjunctivitis and changes in the olfactory and respiratory systems. Can damage the kidneys and liver. At high concentrations, it has narcotic-like action (headaches, dizziness). Also, lachrymation, convulsions loss of coordination, and possible effects on target organs. ABSORPTION: Irritating to the skin, absorbed in toxic amounts. Eye contact may injure cornea. INGESTION: Irritation and narcosis, including drowsiness, salivation, and liver damage. | | | | |
| Carcinogenicity | NTP Listed? | IARC Cancer Review Group? | OSHA Regulated? | Target Organs? |
| Unknown Human Unknown Animal | No | No | 29 CFR 1910.1000 Table Z-1 | Respiratory system, eyes, skin, liver, kidney, CNS. |
| Medical Conditions Generally Aggravated by Exposure None reported. Skin conditions (dermatitis) or respiratory problems (asthma) may be aggravated. | | | | |
| Emergency and First-aid Procedures Eye contact: Flush immediately with water for 15 minutes (minimum); seek medical attention. Skin contact: Remove all contaminated clothing. Immediately wash area with large amounts of soap and water. Seek medical assistance. For inhalation: Remove the person from exposure. Provide respiratory assistance and CPR, if required. Transfer to medical facility. Keep victim warm and at rest. If swallowed: Seek medical attention immediately. Do not induce vomiting unless directed to do so. | | | | |
| SECTION VII - PRECAUTIONS FOR SAFE HANDLING AND USE | | | | |
| Steps to be Taken in Case Material is Released or Spilled Absorb large spills in vermiculite, dry sand, earth, or similar material and deposit in sealed containers. Ventilate area of spill or leak. Restrict those not involved in cleanup from entering area. Remove all sources of ignition. | | | | |
| Preferred Waste Disposal Method Burn in chemical incinerator equipped with an afterburner and scrubber. | | | | |
| Precautions to be Taken in Handling and Storage Store to avoid contact with incompatible materials in tightly closed containers in cool, well-ventilated area away from heat and flame. Use only non-sparking tools to open and close containers. | | | | |
| Other Precautions and Warnings Sources of ignition are prohibited where methylcyclohexanol is used or stored. Heat may cause containers to build up pressure and explode. Containers must be grounded and bonded during transfer. | | | | |
| SECTION VIII - CONTROL MEASURES AND PERSONAL PROTECTIVE EQUIPMENT | | | | |
| Respiratory Protection (specify type) For exposures above the PEL, use an MSHA/NIOSH-approved organic vapor respirator or a supplied-air respirator with full facepiece, hood, or helmet in continuous flow mode, or use a self-contained breathing apparatus (SCBA) operated in pressure demand or other positive pressure mode. | | | | |
| Ventilation Local exhaust or general mechanical systems recommended. | | | | |
| Protective Gloves Impervious Material | | Eye Protection Chemical Goggles or Face Mask | | Other Protective Clothing Protective Apron |
| Work/Hygiene Practices Always wash hands thoroughly after using chemical; never bring food, drink, or smoking materials into vicinity of chemicals. | | | | |

METHYLCYCLOHEXANOL

CAS: 25639-42-3

**IDENTIFICATION AND TYPICAL USES**

Methylcyclohexanol is a straw-colored liquid with a weak odor like that of coconut oil. It is used as a blending agent in textile soaps, as an antioxidant in lubricants, and as a solvent for lacquers.

RISK ASSESSMENT: HEALTH
General Assessment

Methylcyclohexanol is toxic by *ingestion* and *inhalation*. It will also pass through unbroken skin (*absorption*) to cause toxic systemic effects. Its carcinogenicity in humans or animals is not currently known. There are no reports of any carcinogenic or mutagenic effects resulting from exposure to methylcyclohexanol.

Inhalation results in lachrymation, irritation of the throat and upper respiratory tract, headaches, and burning cough. It will irritate the nose, throat, and eyes. Liver and kidney damage can also occur following high or prolonged exposures. Narcotic effects include pronounced dizziness and possible depression of the central nervous system.

Skin and eye contact may produce mild to moderate irritation on contact. It will pass through unbroken skin to cause toxic systemic effects similar to that of inhalation. Absorption through the skin occurring simultaneously with inhalation of methylcyclohexanol vapors may cause serious toxic reactions in the brain, liver, and kidneys.

If ingested, methylcyclohexanol is expected to produce symptoms of irritation and narcosis with salivation, lachrymation, and liver damage.

☠ Acute Health Effects

The following acute (short-term) health effects may occur immediately or shortly after exposure to methylcyclohexanol:

- Skin:** Moderate irritation with redness and possibly painful rash. Will pass through unbroken skin.
- Eye:** Severe irritation and possible corneal injury which may be irreversible depending upon length of contact and concentration of solution.
- Lung:** Nose and throat irritation. Produces intoxicating effects and may damage the lungs.
- CNS:** Unconfirmed effects by all routes of exposure. There may be tremor, dizziness, headache, and other unspecified effects.

☘ Chronic Health Effects

The following chronic (long-term) health effects may occur at some time after exposure to methylcyclohexanol and can last for months or even years:

Cancer Hazards: According to information presented in the references, methylcyclohexanol has not been adequately tested for its ability to cause cancer in animals.

Reproductive Hazard: According to information presented in the references, methylcyclohexanol has not been adequately tested for its ability to cause adverse reproductive effects in test animals.

Other Chronic Effects: Prolonged skin contact may cause drying, cracking, and chapping of the affected area. Repeated or long-term exposures to methylcyclohexanol may affect the liver and kidneys.

🔊 **Recommended Risk-Reduction Measures**

Personnel should avoid direct contact with methylcyclohexanol. Although the acute toxicity of this chemical is believed to be relatively low, the exact nature of its chronic toxicity is not entirely understood in the references. Therefore, prudent risk management requires it be treated as though it posed a significant health risk in the event of overexposure. If a less toxic chemical cannot be substituted for a hazardous substance, then *engineering controls* are the most effective method of reducing exposures. The best protection is to enclose operations and/or provide local exhaust ventilation at the site of chemical release. While not always operationally feasible, isolating operations can also reduce exposure. Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around methylcyclohexanol. For exposures above the PEL, use an organic vapor respirator, a supplied-air respirator with full facepiece operated in continuous flow mode, or a self-contained breathing apparatus (SCBA) with full facepiece and pressure demand as the recommended respiratory protection methods of choice. If a full facepiece is not available, then chemical goggles should be worn to protect the eyes. Whenever a chemical splash hazard exists, a face shield and a protective apron should be worn. To prevent hand and skin exposures, protective gloves should be used. Glove manufacturers should be contacted and permeation studies obtained *before* final glove selections have been made.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with methylcyclohexanol.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where methylcyclohexanol is used or stored.

If symptoms develop or overexposure is suspected, the following tests are recommended:

- ☑ Kidney and liver function tests.
- ☑ Evaluation for nervous system effects.

Any evaluation should include a careful history of past and present symptoms with an examination. Medical tests that simply look for existing damage are not a substitute for controlling exposures.

Other methods to reduce exposure include:

- ☑ Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not used, respiratory protection should be mandatory.
- ☑ Always ensure that proper protective clothing is worn when using chemical substances.
- ☑ Wash thoroughly immediately after exposure to methylcyclohexanol and at the end of the work shift or before eating, drinking, or smoking.
- ☑ Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of methylcyclohexanol should be communicated to all potentially exposed workers.
- ☑ Eye wash stations should be provided in the immediate work area for emergency use. If there is a possibility of skin exposure to methylcyclohexanol, emergency shower facilities should also be provided in the immediate area.
- ☑ Personnel should never wear contaminated clothing home (family members can be exposed). Clothing should be laundered by personnel who have been trained on the hazards of methylcyclohexanol.

RISK ASSESSMENT: ENVIRONMENT

General Assessment

The environment is at risk of exposure during transportation, storage, disposal, or destruction of methylcyclohexanol. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance. Accidental spills, large or small, can result in fire, explosion, and possible contamination of the surrounding environmental mediums (water, soil, and air).

Methylcyclohexanol is considered a Class IIIA combustible liquid (per OSHA 29 CFR 1910.106). It presents a moderate fire hazard in contact with incompatible materials or in vapor form. These characteristics require extreme caution in handling, storage, transportation, and disposal. It is incompatible with

common peroxides and other oxidizers and contact can cause fire or explosion. Therefore, special consideration is required during any emergency situation involving a leak or spill of methylcyclohexanol. Should methylcyclohexanol ever come into contact with these incompatible substances during use, transportation, storage, or disposal, the formation of highly toxic and/or highly explosive commodities (including hydrogen chloride) is extremely possible.

The proper disposal method for methylcyclohexanol is to burn it in a chemical incinerator equipped with an afterburner and scrubber.

Methylcyclohexanol may enter the environment through industrial discharges or spills.

☠ *Acute Ecological Effects*

Acute (short-term) toxic effects may include the death of animals, birds, or fish and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to methylcyclohexanol.

Insufficient data are available on the short-term effects of methylcyclohexanol exposure to aquatic life, birds, plants, or land animals.

🕒 *Chronic Ecological Effects*

Chronic (long-term) toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals.

Insufficient data are available on the long-term effects of methylcyclohexanol exposure to aquatic life, birds, plants, or land animals.

💧 *Water Solubility*

Methylcyclohexanol is nearly insoluble in water. Concentrations of less than 100 milligrams may mix with a liter of water, depending on water pH and chemical concentration of methylcyclohexanol.

🕒 *Persistence in the Environment*

Methylcyclohexanol is non-persistent in water, with a half-life of less than 2 days. The half-life of a pollutant is the amount of time it takes for one half of the chemical to be degraded. Virtually 100% of methylcyclohexanol will eventually end up in air.

🐟 *Bioaccumulation in Aquatic Organisms*

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans.

The concentration of methylcyclohexanol found in fish tissue is expected to be about the same as the average concentration of methylcyclohexanol in the water from which the fish was taken.

🛑 *Recommended Risk-Reduction Measures*

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in a leak or spill to the environment. The correct use of DOT labeling (per the MSDS) on all containers, trucks, and rail cars will enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of methylcyclohexanol should be segregated from incompatible chemicals to minimize the risk of cross-contamination or contact. Buildings designated for storage should be equipped with appropriate fire protection systems (alarms, sprinklers, emergency lighting, portable extinguishers).

If a spill or leak to the environment has occurred, fire department, emergency response and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those trained in proper spill containment procedures using non-sparking tools. Contaminated soils should be removed for incineration and replaced with clean soil. If methylcyclohexanol should contact the water table, aquifer, or navigable waterway, cleanup should be started immediately. It is only slightly soluble in water and total remediation may be possible. The local and/or state emergency response authorities must be notified. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of methylcyclohexanol. If methylcyclohexanol is spilled or leaked, the following specific steps are recommended:

- Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened for normal work.
- Remove all ignition sources.
- Ventilate area of spill or leak. If in confined area, maximum explosion-proof ventilation system may be required.

- ☑ Absorb liquids in vermiculite, dry sand, earth, or similar material and deposit in sealed containers. Use non-sparking tools.
- ☑ It may be necessary to dispose of methylcyclohexanol as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving methylcyclohexanol can present a significant threat to business operations. The loss or damage of equipment or facilities can significantly affect fiscal viability. Lawsuits that may result from personnel injury/death, public exposures, and/or environmental contamination will also require a serious expenditure of resources. Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business.

Recommended Risk-Reduction Measures

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures dealing with safety or emergency response. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

| Extinguishing Media | | Use dry chemical, carbon dioxide, water spray, or alcohol foam (best for large fires). | | | | | |
| Special Fire Fighting Procedures | | Wear full protective clothing and self-contained breathing apparatus (SCBA). Poisonous gases are produced in fire. Use water spray to keep fire-exposed containers cool. Containers may explode in fire. | | | | | |
| Unusual Fire and Explosion Hazards | | Combustible liquid but a dangerous fire hazard when exposed to heat. At high temperatures, forms explosive mixtures with air. Move containers from fire if it can be done without risk. Chemical will react on contact with oxidizable materials. Moderate explosion hazard when in the form of vapor. | | | | | |

| SECTION V - REACTIVITY DATA | | | | |
|---|--------------------------------------|---|---------------------------------------|--|
| Stability | | Conditions to Avoid Normally stable. Keep away from sources of heat (including direct sunlight) or flame. Large quantities should be stored in metal tanks or drums. Keep away from incompatible materials. | | |
| Stable | Unstable | Incompatibility (materials to avoid) | | |
| X | | Strong oxidizers (permanganates, peroxides, nitrates, chlorates, and perchlorates). | | |
| Hazardous Polymerization | | Conditions to Avoid Under normal conditions of temperature and pressure, hazardous polymerization of o-methylcyclohexanone is not expected to occur. | | |
| May Occur | Will Not Occur | Hazardous Decomposition or By-products | | |
| | X | When heated to decomposition, o-methylcyclohexanone can emit highly toxic/poisonous and acrid fumes and gases, including oxides of carbon. | | |
| SECTION VI - HEALTH HAZARD DATA | | | | |
| Primary Route(s) of Entry: | Inhalation? | Absorption (skin)? | Ingestion? | |
| | X | X | X | |
| Health Hazards | | | | |
| INHALATION: Symptoms include salivation, hypothermia, decreased breathing rate, and anesthesia. May also cause central nervous system depression with lung congestion. There can be slight kidney and liver damage with mild narcosis. | | | | |
| ABSORPTION: Irritating to the skin; may cause irritation and dermatitis. An eye irritant with possibility of corneal damage. | | | | |
| INGESTION: Irritation and narcosis, anesthesia, and respiratory difficulties. | | | | |
| Carcinogenicity | NTP Listed? | IARC Cancer Review Group? | OSHA Regulated? | Target Organs? |
| Unknown Human Unknown Animal | No | No | 29 CFR 1910.1000 Table Z-1 | Respiratory system, eyes, skin, liver, kidney, CNS. |
| Medical Conditions Generally Aggravated by Exposure | | | | |
| None reported. Skin conditions (dermatitis) or respiratory problems (asthma) may be aggravated. | | | | |
| Emergency and First-aid Procedures | | | | |
| Eye contact: Flush immediately with water for 15 minutes (minimum); seek medical attention. Skin contact: Remove all contaminated clothing. Immediately wash area with large amounts of soap and water. Seek medical assistance. For inhalation: Remove the person from exposure. Provide respiratory assistance and CPR, if required. Transfer to medical facility. Keep victim warm and at rest. If swallowed: Seek medical attention immediately. Give 1 to 2 glasses of water, then induce vomiting. Never give anything by mouth to an unconscious or convulsing person. | | | | |
| SECTION VII - PRECAUTIONS FOR SAFE HANDLING AND USE | | | | |
| Steps to be Taken in Case Material is Released or Spilled | | | | |
| Absorb in vermiculite, earth, or similar material and deposit in sealed containers. Ventilate area of spill or leak. Restrict those not involved in cleanup from entering area. Remove all sources of ignition. | | | | |
| Preferred Waste Disposal Method | | | | |
| Burn in chemical incinerator equipped with an afterburner and scrubber. | | | | |
| Precautions to be Taken in Handling and Storage | | | | |
| Store to avoid contact with incompatible materials in tightly closed containers in cool, well-ventilated area away from heat and flame. Use only non-sparking tools to open and close containers. | | | | |
| Other Precautions and Warnings | | | | |
| Sources of ignition are prohibited where o-methylcyclohexanone is used, handled, or stored. Heat may cause containers to build up pressure and explode. Ground and bond containers during transfer. | | | | |
| SECTION VIII - CONTROL MEASURES AND PERSONAL PROTECTIVE EQUIPMENT | | | | |
| Respiratory Protection (specify type) | | | | |
| For exposures above the PEL, use an MSHA/NIOSH-approved organic vapor full facepiece respirator. Better protection is obtained from a supplied-air respirator with full facepiece, hood, or helmet in continuous flow mode, or use a self-contained breathing apparatus (SCBA) operated in pressure demand or other positive pressure mode. | | | | |
| Ventilation | | | | |
| Local exhaust or general mechanical systems recommended. | | | | |
| Protective Gloves | Eye Protection | | Other Protective Clothing | |
| Impervious Material | Chemical Goggles or Face Mask | | Protective Apron | |
| Work/Hygiene Practices | | | | |
| Always wash hands thoroughly after using chemical; never bring food, drink, or smoking materials into vicinity of chemicals. | | | | |

***o*-METHYLCYCLOHEXANONE**CH₃C₆H₉O

CAS: 583-60-8

**IDENTIFICATION AND TYPICAL USES**

o-Methylcyclohexanone is a colorless, water-white, to pale yellow, oily liquid with a peppermint-like odor. It is used as a solvent for varnishes, lacquers, and plastics. It is also used in the leather industry and as a rust remover.

RISK ASSESSMENT: HEALTH***General Assessment***

o-Methylcyclohexanone is moderately toxic by *ingestion* and *inhalation*. It will also pass through unbroken skin (*absorption*) to cause toxic systemic effects. Its carcinogenicity in humans and animals is not known. There are no reports in the references on any mutagenic or teratogenic effects in humans or animals resulting from exposure to *o*-methylcyclohexanone.

Inhalation will irritate the nose, throat, and eyes. Mild narcotic properties have also been recorded, including pronounced headache and may cause depression of the central nervous system with symptoms such as headache, dizziness, tiredness, tremor, and loss of consciousness. Kidney and liver damage with mild narcosis may also be possible.

Skin and eye contact may produce mild to moderate irritation. There are also reports of skin absorption occurring on exposure to *o*-methylcyclohexanone. Pure liquid in contact with the eye may result in corneal damage. If ingested, *o*-methylcyclohexanone will produce unspecified gastrointestinal effects.

☠ *Acute Health Effects*

The following acute (short-term) health effects may occur immediately or shortly after exposure to *o*-methylcyclohexanone:

Skin: Will defat the skin and cause irritation and dermatitis. Absorption is likely.

Eye: Severe irritation with a potential for corneal injury or damage.

Lung: Nose and throat irritation. Produces intoxicating effects and may cause lung effects.

CNS: Unconfirmed effects by all routes of exposure. There may be depression, anesthesia, dizziness, headache, and other unspecified effects.

☞ *Chronic Health Effects*

The following chronic (long-term) health effects may occur at some time after exposure to *o*-methylcyclohexanone and can last for months or even years:

Cancer Hazards: According to information presented in the references, *o*-methylcyclohexanone has not been adequately tested for its ability to cause cancer in animals.

Reproductive Hazard: According to information presented in the references, *o*-methylcyclohexanone has not been adequately tested for its ability to adversely affect reproduction in test animals.

Other Chronic Effects: Prolonged skin contact may cause drying, cracking, and chapping of the affected area. There may be skin sensitization and/or dermatitis in some individuals. Repeated or long-term exposures to *o*-methylcyclohexanone may affect the liver and kidneys.

🚫 *Recommended Risk-Reduction Measures*

Personnel should avoid direct contact with *o*-methylcyclohexanone. The exact nature of the toxicity of this chemical is not entirely understood in the references. Therefore, prudent risk management re-

quires it be treated as though it posed a significant health risk in the event of overexposure. If a less toxic chemical cannot be substituted for a hazardous substance, then *engineering controls* are the most effective method of reducing exposures. The best protection is to enclose operations and/or provide local exhaust ventilation at the site of chemical release. While not always operationally feasible, isolating operations can also reduce exposure. Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around chemicals such as *o*-methylcyclohexanone. For exposures above the PEL, a chemical cartridge respirator with a full facepiece, or a supplied-air respirator with full facepiece operated in continuous flow mode, or a self-contained breathing apparatus (SCBA) with full facepiece and pressure demand are the recommended respiratory protection methods of choice. If a full facepiece is not available, then chemical goggles should be worn to protect the eyes. Whenever a chemical splash hazard exists, a face shield and a rubber apron should be worn. To prevent hand and skin exposures, impervious gloves should be worn. Glove manufacturers should be contacted to obtain permeation studies *before* glove selection has been made.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with or around *o*-methylcyclohexanone.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where *o*-methylcyclohexanone is used or stored.

If symptoms develop or overexposure is suspected, the following tests are recommended:

- Kidney and liver function tests.
- Evaluation by a qualified allergist, with careful consideration of exposure history and special skin tests (may help diagnose allergy).
- Lung function tests, including forced vital capacity (FVC).

Any evaluation should include a careful history of past and present symptoms with an examination. Medical tests that simply look for existing damage are not a substitute for controlling exposures. Also, since smoking can cause heart disease, emphysema, and other respiratory disorders, symptoms of exposure to

o-methylcyclohexanone may be more pronounced than those displayed by non-smokers. Proper risk assessment requires careful consideration of *all* possible factors that may be causing the appearance of symptoms in exposed workers.

Other methods to reduce exposure include:

- Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not used, respiratory protection should be mandatory. Also, if possible, automatic transfer of *o*-methylcyclohexanone from storage containers to process or work containers is recommended.
- Always ensure that proper protective clothing is worn when using chemical substances.
- Wash thoroughly immediately after exposure to *o*-methylcyclohexanone and at the end of the work shift or before eating, drinking, or smoking.
- Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of *o*-methylcyclohexanone should be communicated to all potentially exposed workers.
- Eye wash stations should be provided in the immediate work area for emergency use. If there is a possibility of skin exposure to *o*-methylcyclohexanone, emergency shower facilities should also be provided in the immediate area.
- Personnel should never wear contaminated clothing home (family members can be exposed). Clothing should be laundered by personnel who have been trained on the hazards of *o*-methylcyclohexanone.

RISK ASSESSMENT: ENVIRONMENT

General Assessment

The environment is at risk of exposure during transportation, storage, disposal, or destruction of *o*-methylcyclohexanone. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance. Accidental spills, large or small, can result in fire, explosion, and possible contamination of the surrounding environmental mediums (water, soil, and air).

o-Methylcyclohexanone is considered a Class II combustible liquid (per OSHA 29 CFR 1910.106). It presents a moderate fire and explosion hazard risk,

especially in contact with incompatible materials or when its vapors mix with air. These characteristics require extreme caution in handling, storage, transportation, and disposal. It is incompatible with common peroxides and other oxidizers and contact can cause fire or explosion. Therefore, special consideration is required during any emergency situation involving a leak or spill of *o*-methylcyclohexanone. Should this chemical ever come into contact with these incompatible substances during use, transportation, storage, or disposal, the formation of highly toxic and/or highly explosive commodities (including hydrogen chloride) is also extremely possible.

The proper disposal method for *o*-methylcyclohexanone is to burn it in a chemical incinerator equipped with an afterburner and scrubber.

o-Methylcyclohexanone may enter the environment through industrial discharges or spills.

☠ **Acute Ecological Effects**

Acute (short-term) toxic effects may include the death of animals, birds, or fish and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to *o*-methylcyclohexanone.

Insufficient data are available on the short-term effects of *o*-methylcyclohexanone exposure to aquatic life, birds, plants, or land animals.

🕒 **Chronic Ecological Effects**

Chronic (long-term) toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals.

Insufficient data are available on the long-term effects of *o*-methylcyclohexanone exposure to aquatic life, birds, plants, or land animals.

💧 **Water Solubility**

o-Methylcyclohexanone is insoluble in water. Concentrations of less than 1 milligram will not mix with a liter of water.

🕒 **Persistence in the Environment**

No information is available in the references on the persistence of *o*-methylcyclohexanone in the environment.

🐟 **Bioaccumulation in Aquatic Organisms**

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans.

No information is available in the references on the bioaccumulation of *o*-methylcyclohexanone in aquatic organisms.

🛡️ **Recommended Risk-Reduction Measures**

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in a leak or spill to the environment. The correct use of DOT labeling (per the MSDS) on all containers, trucks, and rail cars will enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of *o*-methylcyclohexanone should be segregated from incompatible chemicals to minimize the risk of cross-contamination or contact. Buildings designated for storage should be equipped with appropriate fire protection systems (alarms, sprinklers, emergency lighting, portable extinguishers).

If a spill or leak to the environment has occurred, fire department, emergency response and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those trained in proper spill containment procedures using non-sparking tools. Contaminated soils should be removed for incineration and replaced with clean soil. If *o*-methylcyclohexanone should contact the water table, aquifer, or navigable waterway, cleanup should be started immediately. It is insoluble in water (but highly volatile) and partial remediation may be possible. The local and/or state emergency response authorities must be notified. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of *o*-methylcyclohexanone. If *o*-methylcyclohexanone is spilled or leaked, the following specific steps are recommended:

- Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened for normal work.
- Remove all ignition sources, ventilate area of leak.
- Absorb liquids in vermiculite, dry sand, earth, or similar material and deposit in sealed containers.

- ☑ It may be necessary to dispose of *o*-methylcyclohexanone as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving *o*-methylcyclohexanone can present a significant threat to business operations. The loss or damage of equipment or facilities can significantly affect fiscal viability. Lawsuits that may result from personnel injury/death, public exposures, and/or environmental contamination will also require a serious expenditure of resources. Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business.

Recommended Risk-Reduction Measures

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures dealing with safety or emergency response. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

| Work/Hygiene Practices Always wash hands thoroughly after using chemical; never bring food, drink, or smoking materials into vicinity of chemicals. | | | | |

METHYLENE BROMIDE

CAS: 74-95-3

**IDENTIFICATION AND TYPICAL USES**

Methylene bromide is a colorless, heavy, viscous liquid with a sweet, pleasant, chloroform-like odor. It is used in organic synthesis and as a solvent.

RISK ASSESSMENT: HEALTH***General Assessment***

Methylene bromide is moderately toxic by *inhalation*. While it is somewhat irritating to the skin's surface, dermal absorption has not been reported. Although unlikely under normal operating conditions, *ingestion* is also a possible exposure route. There are no reports of any carcinogenic or teratogenic symptoms resulting from exposure to methylene bromide.

Inhalation is irritating to the eyes, nose, and mucosa of the respiratory tract. High concentrations of methylene bromide causes depression of the central nervous system. Subsequent symptoms include dizziness, lightheadedness, headache, loss of appetite and subsequent weight loss, abdominal pain with progression to major organ system damage (primarily the liver and kidneys), unconsciousness, and death due to liver and kidney damage (necrosis). Other symptoms include general weakness and fatigue, drowsiness, nausea and vomiting, diarrhea, chest pains, cough, and shortness of breath.

Skin contact can produce severe localized irritation and possible dermatitis. Eye contact will also cause irritation to the conjunctiva and surrounding tissues.

☠ *Acute Health Effects*

The following acute (short-term) health effects may occur immediately or shortly after exposure to methylene bromide:

Skin: Irritation with potential for redness, pain, smarting, and dermatitis.

Eye: Irritation and smarting of the conjunctiva. No evidence of permanent damage.

Lung: Irritation of the mucous membranes of the nose, throat, and respiratory tract causing coughing, chest pains, and difficulty breathing.

CNS: Depression of the central nervous system with symptoms of headaches, lightheadedness, dizziness, nausea, vomiting, diarrhea, loss of appetite and weight.

Other: High exposures can lead to rapid progressive damage to the kidneys, liver, heart, and lungs which can lead to death. The heart may beat irregularly or even stop, causing death.

☠* *Chronic Health Effects*

The following chronic (long-term) health effects may occur at some time after exposure to methylene bromide and can last for months or even years:

Cancer Hazards: According to the references, methylene bromide has not been adequately tested for its ability to cause cancer in test animals. However, mutation data have been reported and some scientists believe that such chemicals may pose a cancer risk in the long-term. More research is required in this regard.

Reproductive Hazard: According to information presented in the references, methylene bromide has not been adequately tested for its ability to cause reproductive effects in test animals.

Other Chronic Effects: Repeated skin contact can cause dryness, itching, and irritation. Long-term exposure may lead to liver and kidney damage. Repeated high exposures can cause both bromine and carbon monoxide to accumulate in body tissues.

🕒 **Recommended Risk-Reduction Measures**

Personnel should avoid direct contact with methylene bromide. Occupational poisoning occurs most commonly by inhalation. If a less toxic material or compound cannot be substituted for methylene bromide, then *engineering controls* are the most effective method of reducing exposures. The best protection is to enclose operations and/or provide local exhaust ventilation at the site of methylene bromide release. While not always operationally feasible, isolating operations can also reduce exposure. Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around methylene bromide. Caution should be exercised when selecting respiratory protection since the specific toxic nature of this chemical is not well understood or documented in the references. No exposure limits have been established. However, this does not mean that exposure to methylene bromide is without risk. For best protection, use an MSHA/NIOSH-approved supplied-air respirator with full facepiece and mask operated in positive pressure mode or a self-contained breathing apparatus (SCBA) with full facepiece operated in pressure demand. If a full facepiece is not available, then chemical goggles should be worn to protect the eyes. A face shield should also be considered. To prevent hand and skin exposures, impervious rubber gloves should be used. Glove manufacturers should be contacted and permeation studies obtained *before* final glove selections have been made.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with methylene bromide.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where methylene bromide is used or stored.

Before beginning employment with methylene bromide and at regular intervals thereafter (e.g., annually), the following medical tests are recommended:

- ☑ Liver and kidney function tests (establish baseline).

If symptoms develop or overexposure is suspected, the following tests should be considered:

- ☑ Liver and kidney function tests.
- ☑ Carboxyhemoglobin level tests.
- ☑ Suggest use of Holter monitor (a special, 24-hour EKG monitor that can detect irregular heartbeat).

Any evaluation should include a careful history of past and present symptoms with an examination. Medical tests that simply look for existing damage are not a substitute for controlling exposures. Also, since smoking can cause heart disease, lung cancer, emphysema, and increase carboxyhemoglobin levels, smokers may be affected more rapidly and with more pronounced symptoms than non-smokers. Prudent risk management requires careful consideration of *all* risk factors that might be causing the appearance of symptoms in the work force.

Other methods to reduce exposure include:

- ☑ Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not used, respiratory protection should be mandatory.
- ☑ Always ensure that proper protective clothing is worn when using chemical substances.
- ☑ Wash thoroughly immediately after exposure to methylene bromide and at the end of the work shift or before eating, drinking, or smoking.
- ☑ Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the hazards of methylene bromide should be communicated to all exposed workers.
- ☑ Eye wash stations should be provided in the immediate work area for emergency use. If there is a possibility of skin exposure to methylene bromide, emergency shower facilities should also be provided in the immediate area.
- ☑ Workers whose clothing has been contaminated by methylene bromide should change into clean clothes before leaving work. Contaminated work clothing should be laundered only by individuals who have been informed of the hazards of exposure to methylene bromide.

RISK ASSESSMENT: ENVIRONMENT

General Assessment

The environment is at risk of exposure during transportation, storage, disposal, or destruction of methyl-

ene bromide. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance. Accidental spills, large or small, can result in contamination of the surrounding environmental mediums (water, soil, and air).

Methylene bromide is a non-combustible liquid (it may burn, but does not easily ignite). However, it can react in the presence of chemically-active metals such as potassium to form potentially explosive mixtures. In the presence of heat, it can produce toxic hydrogen bromide. Caution is always required in handling, storage, transportation, and disposal of methylene bromide. Emergency responders should be made aware of the presence of methylene bromide at any emergency response situation.

Methylene bromide can enter the environment from industrial effluents and from spills.

☠ *Acute Ecological Effects*

Acute (short-term) toxic effects may include the death of animals, birds, or fish and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to methylene bromide.

Methylene bromide has slight acute toxicity to aquatic life. Insufficient data are available to evaluate the short-term effects of methylene bromide on plants, birds, or land animals.

☞ *Chronic Ecological Effects*

Chronic (long-term) toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals.

Methylene bromide has slight chronic toxicity to aquatic life. Insufficient data are available to evaluate or predict the long-term effects of methylene bromide to plants, birds, or terrestrial animals.

💧 *Water Solubility*

Methylene bromide is slightly soluble in water. Concentrations of 1 to 100 milligrams will mix with a liter of water.

🕒 *Persistence in the Environment*

Methylene bromide is slightly persistent in water, with a half-life between 2 and 20 days. The half-life of a pollutant is the amount of time it takes for one half of the chemical to be degraded.

🐟 *Bioaccumulation in Aquatic Organisms*

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans.

The concentration of methylene bromide found in fish tissues is expected to be about the same as the average concentration of methylene bromide in the water from which the fish was taken.

🛑 *Recommended Risk-Reduction Measures*

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in a leak or spill of methylene bromide into the environment. Labels on all containers, trucks, and rail cars must meet DOT requirements and accurately reflect their contents to enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of methylene bromide should be segregated from other chemicals and materials to minimize the risk of cross-contamination.

If a spill or leak to the environment has occurred, fire department, emergency response and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those trained in proper spill containment procedures. Contaminated soils should be removed for incineration and replaced with clean soil. If methylene bromide should contact the water table, aquifer, or navigable waterway, the local and/or state emergency response authorities must be notified. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of methylene bromide.

For disposal, methylene bromide may be burned in a chemical incinerator equipped with an afterburner and scrubber.

If methylene bromide is spilled or leaked, the following specific steps are recommended:

- ☑ Restrict persons not wearing protective clothing from area of spill until cleanup is complete and area can be opened for normal work.
- ☑ Absorb liquids in vermiculite, sand, earth, or similar material and deposit in sealed drum. Avoid breathing vapors of methylene bromide.
- ☑ Ventilate area of spill or leak.
- ☑ Remove all sources of heat and ignition.

- ☑ It may be necessary to dispose of methylene bromide as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving methylene bromide can present a serious threat to business operations. The loss or damage of equipment or facilities can significantly affect fiscal viability. Lawsuits that may result from personnel illness, injury/death, public exposures, and/or environmental contamination will require a serious expenditure of resources. Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business.

Recommended Risk-Reduction Measures

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures for responding to chemical incidents. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

Extinguishing Media
Dry chemical, carbon dioxide, alcohol foam, water spray/fog, or dry sand. Direct water may be ineffective.

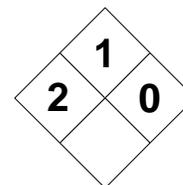

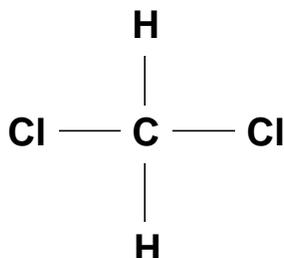

Special Fire Fighting Procedures
Poisonous gases are produced in fire. Wear self-contained breathing apparatus (SCBA) and full protective gear. Move containers from fire if it can be done without risk. Cool sides of fire-exposed containers with water until long after fire is out.

Unusual Fire and Explosion Hazards
Containers may explode in fire. Stay away from ends of tanks. Evacuate 1500 feet if rising sound is heard coming from venting device or sides of tank become discolored due to heat of fire.

| SECTION V - REACTIVITY DATA | | | | |
|---|----------------------------|--|---------------------------------------|--|
| Stability | | Conditions to Avoid Methylene chloride is normally stable. Avoid heat, flame, other sources of ignition, and contact with incompatible materials and chemicals. | | |
| Stable X | Unstable | Incompatibility (<i>materials to avoid</i>) Strong oxidizers (chlorine, bromine, fluorine), chemically active metals (such as sodium, potassium, calcium, powdered aluminum, zinc, and magnesium), caustic agents, and concentrated nitric acid. | | |
| Hazardous Polymerization | | Conditions to Avoid Under normal conditions of temperature and pressure, hazardous polymerization of methylene chloride cannot occur. | | |
| May Occur | Will Not Occur X | Hazardous Decomposition or By-products Poisonous gases and acrid fumes are produced in fire, including extremely toxic phosgene gas and carbon monoxide fumes. | | |
| SECTION VI - HEALTH HAZARD DATA | | | | |
| Primary Route(s) of Entry: | | Inhalation? X | Absorption (skin/eye)? X | Ingestion? X |
| Health Hazards INHALATION: Respiratory irritation, intoxication, narcotic and anesthetic effects, vomiting, dizziness, depression, diarrhea, CNS depression, eye irritation, digestive disturbances, leukocytosis, fatigue, lack of motivation, psychosomatic symptoms, increase in carboxyhemoglobin content of the blood, numbness, pulmonary edema, unconsciousness, and death. ABSORPTION: Irritation, de-fatting, and burning of the skin surface. Eye contact may result in severe irritation and possible damage. Will pass through intact skin and cause toxic effects. INGESTION: Gastrointestinal irritation along with symptoms similar to that of inhalation. | | | | |
| Carcinogenicity | NTP Listed? | IARC Cancer Review Group? | OSHA Regulated? | Target Organs? |
| Suspected Human Confirmed Animal | Class 2 | Group 2B | 29 CFR 1910.1000 Table Z-1 | Eyes, skin, resp. sys., liver, kidney, CVS, CNS. |
| Medical Conditions Generally Aggravated by Exposure Skin and cardiovascular disorders may be aggravated by exposure. | | | | |
| Emergency and First-aid Procedures Eye contact: Do not allow victim to keep eyes shut. Flush immediately with water for 15 minutes minimum; seek medical attention. Skin contact: Remove all contaminated clothing. Immediately wash area with flooding amounts of soap and water. Seek medical attention immediately. For inhalation: Remove the person from exposure. Provide respiratory assistance and CPR. Transfer to medical facility. Observe for 48 hours for lung effects. If swallowed: Seek medical attention immediately. Induce vomiting in conscious and alert person. Never give an unconscious or convulsing person anything by mouth. | | | | |
| SECTION VII - PRECAUTIONS FOR SAFE HANDLING AND USE | | | | |
| Steps to be Taken in Case Material is Released or Spilled Remove all ignition sources, wear SCBA respiratory protection. Restrict those not wearing protective equipment who are not involved in cleanup from entering area. Absorb with vermiculite and place in sealed container. Flush residues with water (keep away from sewers). | | | | |
| Preferred Waste Disposal Method Burn in chemical incinerator equipped with an afterburner and scrubber. | | | | |
| Precautions to be Taken in Handling and Storage Store in tightly closed containers in cool, well-ventilated location. Keep away from sources of heat. | | | | |
| Other Precautions and Warnings Sources of ignition are prohibited where methylene chloride is used or stored. Metal containers should be bonded and grounded. Empty cylinders contain residue; handle with care. | | | | |
| SECTION VIII - CONTROL MEASURES AND PERSONAL PROTECTIVE EQUIPMENT | | | | |
| Respiratory Protection (<i>specify type</i>) Use an MSHA/NIOSH-approved air purifying respirator (cartridge type) or use a supplied-air respirator or a self-contained breathing apparatus (SCBA) with full facepiece operated in positive pressure mode. | | | | |
| Ventilation Local exhaust (preferred) at site of chemical work or general ventilation. | | | | |
| Protective Gloves Impervious Rubber Gloves | | Eye Protection Chemical Goggles or Face Mask | | Other Protective Clothing Protective Apron if Splash is Likely |
| Work/Hygiene Practices Always wash hands thoroughly after using chemical; never bring food, drink, or smoking materials into vicinity of chemicals. | | | | |

METHYLENE CHLORIDE

CAS: 75-09-2

**IDENTIFICATION AND TYPICAL USES**

Methylene chloride is a colorless liquid with a sweet odor. It is widely used as a solvent, a degreaser, and a cleaning reagent. It is also used in paint removers, and in extractions of organic compounds from water for analyses. It is a blowing agent for foams, a solvent for cellulose acetate, and is used as an aerosol propellant.

RISK ASSESSMENT: HEALTH**General Assessment**

Methylene chloride is mildly toxic by *inhalation*. The liquid is also known to pass through the skin (*absorption*) to cause toxic systemic effects, and it is considered moderately toxic by *ingestion*. This chemical is known to cause cancer in test animals (liver and lung) and this effect is suspected to occur in humans as well. Human mutation data have been reported. In addition, methylene chloride has been shown to adversely affect reproduction in test animals. The systemic effects of overexposure can be seen in the liver, kidneys, digestive tract, blood, lungs, and in the central nervous system.

Inhalation is irritating to the eyes, nose, and mucosa of the respiratory tract and may produce ulceration of the mucous membrane. High concentrations of methylene chloride causes depression of the central nervous system (CNS). Symptoms include dizziness, intoxication, narcotic and anesthetic effects, lightheadedness, headache, somnolence, cyanosis, unconsciousness, coma, and death.

This chemical poses a significant hepatotoxic threat (injurious to the liver). Irritation to lung tissues can lead to a dangerous buildup of fluids in the lungs (pulmonary edema), which is a medical emergency and can be fatal. Symptoms may be delayed up to 48

hours creating a false sense of security with regard to health risk. Exposure can also cause the heart to beat irregularly or even stop which, of course, can be fatal.

Skin contact can produce severe localized irritation, burns, de-fatting of the surface leading to possible cracking, drying, and secondary infections. Absorption will occur rapidly causing an increase in toxicity. If coupled with inhalation, the systemic effects can be quite severe. Eye contact will also cause irritation and, if not removed immediately, conjunctivitis.

Ingestion can result in gastrointestinal irritation and systemic symptoms similar to that of inhalation.

☠ Acute Health Effects

The following acute (short-term) health effects may occur immediately or shortly after exposure to methylene chloride:

- Skin:** Irritation with potential for redness, pain, burns, and tissue damage.
- Eye:** Irritation and smarting of the conjunctiva. Can cause tearing, redness, and pain.
- Lung:** Irritation of the mucous membranes of the nose, throat, and respiratory tract causing possible ulceration, coughing, chest pains, difficulty breathing, and pulmonary edema.
- CNS:** Depression with headaches, lightheadedness, dizziness, nausea, vomiting, diarrhea, narcotic and anesthetic effects.

☘ Chronic Health Effects

The following chronic (long-term) health effects may occur at some time after exposure to methylene chloride and can last for months or even years:

Cancer Hazards: According to the references, methylene chloride in a confirmed animal carcinogen and

several agencies consider methylene chloride to be a potential or suspect human carcinogen. These include the IARC (International Association for Research on Cancer), the NTP (National Toxicology Program), and the ACGIH (American Conference of Governmental Industrial Hygienists). It has caused cancer of the lung and liver in animals. Human mutation data have also been reported.

Reproductive Hazard: According to information presented in the references, methylene chloride is a possible teratogen in animals and has been shown to adversely affect reproduction in test animals. It is not known if exposure to methylene chloride will have this effect on humans.

Other Chronic Effects: Methylene chloride may irritate the lungs. This is more likely to occur if the chemical is used near a combustion source (furnace, welding) since phosgene (a lung-damaging gas) is released. Repeated exposures may cause bronchitis with cough, phlegm, and/or shortness of breath. Higher exposures may damage the liver. Long-term exposure may damage the brain, causing memory loss, poor coordination, and reduced thinking ability. Repeated skin exposure can cause thickening and cracking of the skin.

🔑 **Recommended Risk-Reduction Measures**

Personnel should avoid direct contact with methylene chloride. It is a highly toxic, known cancer-causing agent. There may be no safe exposure level to methylene chloride. Occupational poisoning occurs most commonly by inhalation and skin absorption. If a less toxic material or compound cannot be substituted for methylene chloride, then *engineering controls* are the most effective method of reducing exposures. The best protection is to enclose operations and/or provide local exhaust ventilation at the site of methylene chloride release. While not always operationally feasible, isolating operations can also reduce exposure. Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around methylene chloride. Caution should be exercised when selecting respiratory protection since it is not known if exposure to methylene chloride will cause cancer in humans. Many reference sources also indicate that the established PEL of 500 ppm is outdated and insufficient to protect against harmful exposures. Risk managers should consider the known evidence regarding methylene chloride's toxicity and act accordingly, regardless of established exposure levels. A conservative approach to a carcinogenic material may be prudent. For the best pro-

tection against a *possible carcinogen*, especially when the concentration is unknown, use a supplied-air respirator with full facepiece and mask operated in positive pressure mode or a self-contained breathing apparatus (SCBA) with full facepiece operated in pressure demand. If a full facepiece is not available, then chemical goggles should be worn to protect the eyes. A face shield should also be considered. To prevent hand and skin exposures, impervious rubber gloves should be used. Glove manufacturers should be contacted and permeation studies obtained *before* final glove selections have been made.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with methylene chloride.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where methylene chloride is used or stored.

Before beginning employment with methylene chloride and at regular intervals thereafter (e.g., annually), the following medical tests are recommended:

Liver and kidney function tests (establish baseline).

Lung function tests (establish baseline).

If symptoms develop or overexposure is suspected, the following tests should be considered:

Liver and kidney function tests.

Suggest Holter monitor (special 24-hour EKG) to detect irregular heartbeat.

Blood carboxyhemoglobin within a few hours of exposure.

Interview for brain effects, including recent memory or mood changes (irritability, withdrawal), concentration problems, headaches, malaise, and altered sleep patterns. Consider cerebellar, autonomic, and peripheral nervous system evaluation. Positive and borderline individuals should be referred neuropsychological testing.

Consider chest X-ray after acute overexposure (may be negative if taken immediately after exposure due to delayed onset of pulmonary edema).

Lung function tests (compare to baseline).

Any evaluation should include a careful history of past and present symptoms with an examination. Medical tests that simply look for existing damage are not a

substitute for controlling exposures. Also, since smoking can cause heart disease, lung cancer, increase carboxyhemoglobin levels, emphysema, and other respiratory problems, smokers may be affected more rapidly and with more pronounced symptoms than non-smokers. Prudent risk management requires careful consideration of *all* risk factors that might be causing the appearance of symptoms in the work force.

Other methods to reduce exposure include:

- ☑ Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not feasible, then respiratory protection should be provided and its use mandatory.
- ☑ Always ensure that proper protective clothing is worn when using chemical substances.
- ☑ Wash thoroughly immediately after exposure to methylene chloride and at the end of the work shift or before eating, drinking, or smoking.
- ☑ Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of methylene chloride should be communicated to all potentially exposed workers.
- ☑ Eye wash stations should be provided in the immediate work area for emergency use. If there is a possibility of skin exposure to methylene chloride, emergency shower facilities should also be provided in the immediate work area.
- ☑ Workers whose clothing has been contaminated by methylene chloride should change into clean clothes before leaving work. Contaminated work clothing should be laundered only by individuals who have been informed of the hazards of exposure to methylene chloride.

RISK ASSESSMENT: ENVIRONMENT

General Assessment

The environment is at risk of exposure during transportation, storage, disposal, or destruction of methylene chloride. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance. Accidental spills, large or small, can result in contamination of the surrounding environmental mediums (water, soil, and air).

Methylene chloride is a mildly combustible liquid but it can form explosive mixtures in air. It is a moderate explosion hazard in closed containers when exposed to heat or flame. It can also react violently in the presence of chemically-active metals such as sodium, potassium, calcium, and strong oxidizing agents. Caution is always required in handling, storage, transportation, and disposal of methylene chloride. A phenomenon known as a boiling liquid expanding vapor explosion (BLEVE) can occur when tanks, containers, or rail cars containing methylene chloride are involved in a fire. The pressure that builds inside the container can explode violently and without much warning. Emergency responders should, therefore, be made aware of the presence of methylene chloride at any emergency response situation. Methylene chloride can enter the environment from industrial effluents and from spills.

☠ *Acute Ecological Effects*

Acute (short-term) toxic effects may include the death of animals, birds, or fish and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to methylene chloride. Methylene chloride has moderate acute toxicity to aquatic life. It has caused both increases and decreases in seed germination in various agricultural crops. Insufficient data are available to evaluate the short-term effects of methylene chloride on birds or land animals.

☪ *Chronic Ecological Effects*

Chronic (long-term) toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals. Methylene chloride has moderate chronic toxicity to aquatic life. Insufficient data are available to evaluate the long-term effects of methylene chloride to plants, birds, or terrestrial animals.

💧 *Water Solubility*

Methylene chloride is slightly soluble in water. Concentrations of 1 to 100 milligrams will mix with a liter of water.

🕒 *Persistence in the Environment*

Methylene chloride is slightly persistent in water, with a half-life between 2 and 200 days. The half-life of a pollutant is the amount of time it takes for one half of

the chemical to be degraded. About 99% of methylene chloride will eventually end up in air, the rest will end up in the water.

🐟 Bioaccumulation in Aquatic Organisms

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans. The concentration of methylene chloride found in fish tissues is expected to be about the same as the average concentration of methylene chloride in the water from which the fish was taken.

🚫 Recommended Risk-Reduction Measures

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in a leak or spill of methylene chloride into the environment. Labels on all containers, trucks, and rail cars must meet DOT requirements and accurately reflect their contents to enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of methylene chloride should be segregated from other chemicals and materials to minimize the risk of cross-contamination.

If a spill or leak to the environment has occurred, fire department, emergency response and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those trained in proper spill containment procedures. Contaminated soils should be removed for incineration and replaced with clean soil. If methylene chloride should contact the water table, aquifer, or navigable waterway, time is of the essence. It is only slightly soluble and total remediation may be possible. The local and/or state emergency response authorities must be notified. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of methylene chloride.

For disposal, methylene chloride may be burned in a chemical incinerator equipped with an afterburner and scrubber. If methylene chloride is spilled or leaked, the following specific steps are recommended:

- Remove ignition sources and ventilate area of spill or leak.
- It may be necessary to dispose of methylene chloride as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

- Restrict persons not wearing protective clothing from area of spill until cleanup is complete.
- Absorb liquids in vermiculite, sand, earth, or similar material and deposit in sealed drum.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving methylene chloride can present a serious threat to business operations. The loss or damage of equipment or facilities can significantly affect fiscal viability. Lawsuits that may result from personnel illness, injury/death, public exposures, and/or environmental contamination will require a serious expenditure of resources. Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business. Always remember that anytime the terms “cancer,” “carcinogen,” or “reproductive hazard” are used, public emotion, hysteria, and ignorance can run equally high. This must be carefully considered when developing any public relation policies.

🚫 Recommended Risk-Reduction Measures

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures for responding to chemical incidents. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

| Stable X | Unstable | Incompatibility (<i>materials to avoid</i>) Strong oxidizers (such as perchlorates, peroxides, permanganates, chlorates and nitrates); strong acids (such as hydrochloric, sulfuric, and nitric). | | |
| Hazardous Polymerization | | Conditions to Avoid Under normal conditions of temperature and pressure, hazardous polymerization of 4,4-methylenedianiline is not expected to occur. | | |
| May Occur | Will Not Occur X | Hazardous Decomposition or By-products When heated to decomposition, 4,4-methylenedianiline can emit highly toxic/poisonous gases, including carbon monoxide and toxic aniline vapors. | | |
| SECTION VI - HEALTH HAZARD DATA | | | | |
| Primary Route(s) of Entry: | | Inhalation? X | Absorption (skin)? X | Ingestion? |
| Health Hazards INHALATION: Causes abrupt onset of upper abdominal pain accompanied by fever, jaundice, rigidity, and liver changes. There can also be visual disturbances (loss of visual acuity, color discrimination, and dark adaptation). A dangerous liver toxin. Also causes an increase in the carboxyhemoglobin levels of the blood. ABSORPTION: Absorbs freely through intact skin. Also causes headache and symptoms similar to that of inhalation. Skin discoloration is also likely (to yellow or faint brown). INGESTION: Unspecified effects resulting from ingestion. Liver damage is suspect. | | | | |
| Carcinogenicity Suspected Human Confirmed Animal | NTP Listed? 5th Annual Report | IARC Cancer Review Group? Group 2B | OSHA Regulated? 29 CFR 1910.1050 | Target Organs? Eyes, liver, CVS, spleen, skin. |
| Medical Conditions Generally Aggravated by Exposure Existing liver diseases may be aggravated by exposure. | | | | |
| Emergency and First-aid Procedures <u>Eye contact:</u> Flush immediately with water for 15 minutes (minimum); seek medical attention. <u>Skin contact:</u> Remove all contaminated clothing. Immediately wash area with large amounts of soap and water. Seek medical assistance. For <u>inhalation:</u> Remove the person from exposure. Provide respiratory assistance and CPR. Transfer to medical facility. If <u>swallowed:</u> Seek medical attention immediately. Unless advised otherwise, give 2-3 glasses of water to a conscious person and induce vomiting. | | | | |
| SECTION VII - PRECAUTIONS FOR SAFE HANDLING AND USE | | | | |
| Steps to be Taken in Case Material is Released or Spilled Shovel, vacuum, or damp mop spilled methylenedianiline and place in sealed drums for disposal. Avoid generating airborne dusts. Ventilate area of spill or leak. Restrict those not involved in cleanup from entering area. | | | | |
| Preferred Waste Disposal Method No citation. | | | | |
| Precautions to be Taken in Handling and Storage Store in tightly closed containers in cool, well-ventilated area away from heat. Protect containers from physical damage and protect from exposure to direct sunlight. This chemical is suspected to cause cancer in humans. Avoid skin contact and inhalation of airborne dusts or fumes. | | | | |
| Other Precautions and Warnings Sources of ignition are prohibited where 4,4-methylenedianiline is used, handled, or stored. Bulk storage of 4,4-methylenedianiline should be kept in isolated or detached buildings or facilities. | | | | |
| SECTION VIII - CONTROL MEASURES AND PERSONAL PROTECTIVE EQUIPMENT | | | | |
| Respiratory Protection (<i>specify type</i>) Exposure level is extremely low and difficult to monitor. Suggest a self-contained breathing apparatus with full facepiece operated in positive pressure mode for protection against suspected carcinogen. | | | | |
| Ventilation Local exhaust at site of chemical work. | | | | |
| Protective Gloves Impervious Rubber | Eye Protection Chemical Goggles or Face Mask | Other Protective Clothing Rubber Apron | | |
| Work/Hygiene Practices Always wash hands thoroughly after using chemical; never bring food, drink, or smoking materials into vicinity of chemicals. | | | | |

4,4-METHYLENEDIANILINE

CAS: 101-77-9

**IDENTIFICATION AND TYPICAL USES**

4,4-Methylenedianiline is a light brown, tan, or amber crystalline solid with a faint, characteristic amine odor. It is used in the determination of tungsten and sulfates, as a polymer and dye intermediate, as a corrosion inhibitor, as an epoxy-resin hardening agent, in isocyanate resins, and in polyimides.

RISK ASSESSMENT: HEALTH***General Assessment***

4,4-Methylenedianiline is a human poison by *inhalation* and skin contact (*absorption*). It is known to cause cancer in test animals and is considered a suspected human carcinogen. Mutation data have also been reported. There is no information in the references regarding its teratogenic effects on animals or humans.

Inhalation and dermal absorption is likely to cause systemic poisoning characterized by symptoms that reflect liver involvement. These include jaundice, upper abdominal pain, and hepatitis. Other symptoms of exposure include rigidity, visual disturbances (loss of central visual acuity, color discrimination, and dark adaptation), and a marked increase in the carboxyhemoglobin content of the blood. The latter reduces the blood ability to transport oxygen to the cells of the body and can lead to serious illness.

Eye and skin contact will result in irritation. More importantly, however, is the fact that this compound is absorbed through intact skin on prolonged exposure causing the same toxic systemic effects as that noted for inhalation. Combined exposures (inhalation and absorption) can therefore pose a serious health risk.

☠ *Acute Health Effects*

The following acute (short-term) health effects may occur immediately or shortly after exposure to 4,4-methylenedianiline:

Skin: Irritation and absorption through unbroken skin. Skin discoloration (to light brown or yellow) is common.

Eye: Severe irritation with possible corneal damage.

Lung: Irritation of the nose, throat, and upper respiratory tract. Easily absorbed and distributed through the respiration process to cause toxic systemic effects primarily involving the liver.

CVS: 4,4-Methylenedianiline affects the blood's ability to transport oxygen (increase in carboxyhemoglobin content of blood).

☞* *Chronic Health Effects*

The following chronic (long-term) health effects may occur at some time after exposure to 4,4-methylenedianiline and can last for months or even years:

Cancer Hazards: 4,4-Methylenedianiline has been shown to cause cancer in test animals and its carcinogenic potential in humans is considered highly suspect. Mutation data have also been confirmed.

Reproductive Hazard: According to information presented in the references, 4,4-methylenedianiline has not been adequately tested for its ability to adversely affect reproduction.

Other Chronic Effects: Continuous exposure to small doses of 4,4-methylenedianiline may produce anemia, loss of energy, digestive disturbance, and headache. Repeated exposures may cause anemia and an increase in carboxyhemoglobin levels to occur gradually over time rather than all at once. Skin discoloration to light brown or yellow is common on prolonged exposures. There may also be the appearance of vertical brown streaks under the finger nails. This indicates repeated overexposures. Liver involvement may also be occurring at this stage.

🕒 **Recommended Risk-Reduction Measures**

Personnel should avoid direct contact with 4,4-methylenedianiline. It is a suspected human carcinogen and there may be no safe exposure level. If a less toxic chemical cannot be substituted for a hazardous substance, then *engineering controls* are the most effective method of reducing exposures. The best protection is to enclose operations and/or provide local exhaust ventilation at the site of chemical release. While not always operationally feasible, isolating operations can also reduce exposure. Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around 4,4-methylenedianiline. The exposure level is extremely low (0.010 ppm) and difficult to accurately monitor, especially in emergency situations. For the best protection against suspected carcinogens, recommend using a self-contained breathing apparatus (SCBA) with full facepiece operated in pressure demand or a supplied-air respirator operated in positive pressure mode. If a full facepiece is not available, then chemical goggles should be worn to protect the eyes. 4,4'-Methylenedianiline is often mixed in a thick liquid with other chemical agents and, therefore, whenever a chemical splash hazard exists, a face shield and a rubber apron should be worn. Skin contact must be prevented. To prevent hand and skin exposures, impervious rubber gloves should be used. This chemical is known to have peculiar permeation characteristics. Glove manufacturers should therefore be contacted and permeation studies reviewed *before* final glove selections are made. Providing the wrong glove creates a false sense of security and can present a more serious health hazard risk than no protection at all.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with or around 4,4-methylenedianiline.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication) as well as OSHA 1910.1050 (4,4'-Methylenedianiline), prior to their first assignment in an area where 4,4-methylenedianiline is used or stored.

If symptoms develop or overexposure is suspected, the following medical tests may be useful:

- Carboxyhemoglobin level tests.
- Liver function tests

Any evaluation should include a careful history of past and present symptoms with an examination. Medical tests that simply look for existing damage are not a substitute for controlling exposures. Also, since smoking can increase carboxyhemoglobin levels as well as cause other serious health effects, smokers exposed to 4,4-methylenedianiline may experience symptoms more rapidly than non-smokers under the same conditions of exposure. Prudent risk management requires careful consideration of *all* possible risk factors.

Other methods to reduce exposure include:

- Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not used, respiratory protection should be mandatory.
- Always ensure that proper protective clothing is worn when using chemical substances.
- Safety showers should be provided in areas where work is performed around 4,4-methylenedianiline.
- Wash thoroughly immediately after exposure to 4,4-methylenedianiline and at the end of the work shift or before eating, drinking, or smoking.
- Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards associated with 4,4-methylenedianiline should be communicated to all potentially exposed workers.
- Eye wash stations should be provided in the immediate work area for emergency use. If there is a possibility of skin exposure of any degree to 4,4-methylenedianiline, emergency shower facilities should also be provided.

RISK ASSESSMENT: ENVIRONMENT

General Assessment

The environment is at risk of exposure during transportation, storage, disposal, or destruction of 4,4-methylenedianiline. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance. Accidental spills, large or small, can result in fire, explosion, and possible contamination of the surrounding environmental mediums (water, soil, and air).

4,4-Methylenedianiline is considered a combustible solid. However, because it is incompatible with

so very many other common commodities (such as oxidizers and acids), extreme caution is required in handling, storage, transportation, and disposal of 4,4-methylenedianiline. These characteristics also require special consideration during any emergency situation involving a leak or spill of 4,4-methylenedianiline. Should 4,4-methylenedianiline ever come into contact with incompatible substances either during use, transportation, storage, or disposal, the formation of highly toxic and/or highly explosive commodities is possible.

4,4-Methylenedianiline can enter the environment through industrial and municipal waste treatment plant discharges, or from spills.

☠ *Acute Ecological Effects*

Acute (short-term) toxic effects may include the death of animals, birds, or fish and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to 4,4-methylenedianiline. Insufficient data are available to evaluate or predict the short-term effects of 4,4-methylenedianiline to aquatic life, plants, birds, or land animals.

🕒 *Chronic Ecological Effects*

Chronic (long-term) toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals. Insufficient data are available on the long-term effects of 4,4-methylenedianiline to aquatic life, plants, birds, or land animals.

💧 *Water Solubility*

4,4-methylenedianiline is slightly soluble in water. Concentrations of 1 to 100 milligrams will mix with a liter of water.

🕒 *Persistence in the Environment*

4,4-Methylenedianiline is highly persistent in water, with a half-life between 20 and 200 days. The half-life of a pollutant is the amount of time it takes for one half of the chemical to be degraded.

🌊 *Bioaccumulation in Aquatic Organisms*

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become con-

centrated in the tissues and internal organs of animals as well as humans.

The concentration of 4,4-methylenedianiline found in fish tissues is expected to be about the same as the average concentration of 4,4-methylenedianiline in the water from which the fish was taken.

🛑 *Recommended Risk-Reduction Measures*

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in a leak or spill to the environment. The correct use of DOT labeling (per the MSDS) on all containers, trucks, and rail cars will enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of 4,4-methylenedianiline should be segregated from incompatible chemicals to minimize the risk of cross-contamination or contact.

If a spill or leak to the environment has occurred, fire department, emergency response and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those trained in proper spill containment procedures. Contaminated soils should be removed for incineration and replaced with clean soil. If 4,4-methylenedianiline should contact the water table, aquifer, or navigable waterway, the local and/or state emergency response authorities must be notified. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of 4,4-methylenedianiline. If 4,4-methylenedianiline is spilled or leaked, the following specific steps are recommended:

- Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened for normal.
- Remove all ignition sources.
- Shovel, vacuum, or damp mop spilled materials and place in sealed drums for reclamation or disposal. Avoid generating excessive amounts of airborne dusts during cleanup operations.
- It may be necessary to dispose of 4,4-methylenedianiline as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Risk Management for Hazardous Chemicals

Accidents or mishaps involving 4,4-methylenedianiline can present a significant threat to business operations. The loss or damage of equipment or facilities can significantly affect fiscal viability. Lawsuits that may result from personnel injury/death, public exposures, and/or environmental contamination will also require a serious expenditure of resources. Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business. Always remember that anytime the terms "cancer" or "carcinogen" are used, public hysteria, emotion, and ignorance can run equally high. This should be carefully considered whenever developing or implementing public relation policies.

Recommended Risk-Reduction Measures

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures dealing with safety or emergency response. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

Solubility

Soluble in water (28%). Soluble in alcohol, benzene, and ether. Miscible in fixed oils.

Appearance and Odor

Colorless liquid with a sweet mint or acetone-like odor. Odor Threshold = 25 ppm.

SECTION IV - FIRE AND EXPLOSION HAZARD DATA

| | |
|--|--|
| Flash Point (method used) 16°F (-9°C) closed cup | Explosive Limits in Air % by Volume LEL: 1.4% at 200 UEL: 11.4% at 200°F |
| NFPA Classification Class 1B Flammable Liquid | Autoignition Temperature 759°F (404°C) |

Extinguishing Media

Dry chemical, carbon dioxide, water spray, fog, or alcohol-resistant foam.

Special Fire Fighting Procedures

Poisonous gases are produced in fire. Wear full protective clothing and self-contained breathing apparatus. Fight fire from a distance if possible. Keep fire-exposed containers cool with water spray. A solid stream of water may spread fire. If it can be done safely, move fire-exposed containers from area.

Unusual Fire and Explosion Hazards

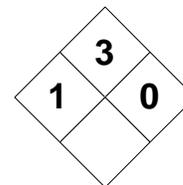

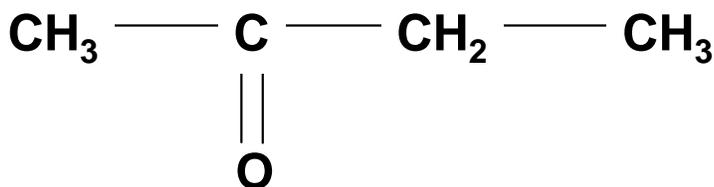

Containers may explode in fire due to the buildup of internal pressures. BLEVE (boiling liquid expanding vapor explosion) is possible. Immediately evacuate if rising sound is heard from venting device or a noticeable discoloration is observed on the sides of the tank or storage vessel.

SECTION V - REACTIVITY DATA

| | | | | |
|--|----------------------------|--|---------------------------------------|---|
| Stability | | Conditions to Avoid Normally stable. Do not allow methyl ethyl ketone to come into contact with incompatible materials. Avoid contact with fire or high heat sources. Do not use in confined spaces. | | |
| Stable X | Unstable | Incompatibility (<i>materials to avoid</i>) Incompatible with chlorosulfonic acid, fuming sulfuric acid, potassium-<i>t</i>-butoxide, hydrogen peroxide + nitric acid, 2-propanol, chloroform + alkali, amines, ammonia, inorganic acids, caustics, copper, oxidizers. | | |
| Hazardous Polymerization | | Conditions to Avoid Under normal conditions of temperature and pressure, hazardous polymerization of methyl ethyl ketone is not expected to occur. Methyl ethyl ketone will dissolve some plastics. | | |
| May Occur | Will Not Occur X | Hazardous Decomposition or By-products When heated to decomposition, methyl ethyl ketone emits acrid, irritating smoke and fumes, including oxides of carbon. | | |
| SECTION VI - HEALTH HAZARD DATA | | | | |
| Primary Route(s) of Entry: | | Inhalation? X | Absorption (skin)? X | Ingestion? |
| Health Hazards | | | | |
| INHALATION: Irritation of the mucosa of the respiratory tract causing respiratory depression with gasping, choking, and dyspnea. Higher concentrations causes CNS depression with headache, dizziness, fainting, tremor, chemical pneumonitis, coma, and possibly death. | | | | |
| ABSORPTION: Skin contact with liquid or vapor can result in irritation and may cause dermatitis and paresthesia (tingling). Eye contact causes pain, irritation, and corneal damage, tearing. | | | | |
| INGESTION: Unlikely. Symptoms of irritation, sore throat, nausea, coughing, salivation, vomiting. | | | | |
| Carcinogenicity | NTP Listed? | IARC Cancer Review Group? | OSHA Regulated? | Target Organs? |
| Unknown Human Unknown Animal | No | No | 29 CFR 1910.1000 Table Z-1 | Respiratory system; skin; eyes; CNS. |
| Medical Conditions Generally Aggravated by Exposure Skin conditions (dermatitis) may be aggravated. | | | | |
| Emergency and First-aid Procedures | | | | |
| Eye contact: Immediately flush large amounts of water for 15 minutes (minimum); occasionally lifting eyelids. Skin contact: Remove all contaminated clothing. Immediately wash area with large amounts of soap and water. For inhalation: Remove the person from exposure. Provide respiratory assistance and CPR. Transfer promptly to medical facility. If swallowed: Seek medical attention immediately. Give a conscious and alert victim several glasses of milk or water. The decision to induce vomiting must be carefully considered (it may cause direct aspiration of the liquid leading to chemical pneumonitis). | | | | |
| SECTION VII - PRECAUTIONS FOR SAFE HANDLING AND USE | | | | |
| Steps to be Taken in Case Material is Released or Spilled | | | | |
| Remove all ignition sources. Restrict persons not wearing protective equipment from entering area of spill or leak until cleanup is complete. Ventilate area. Absorb liquid in dry sand or other material and deposit in sealed containers. Damp mop residue. Alert appropriate state or federal response agencies. | | | | |
| Preferred Waste Disposal Method | | | | |
| Burn in a chemical incinerator equipped with an afterburner and scrubber. | | | | |
| Precautions to be Taken in Handling and Storage | | | | |
| Do not store with incompatible chemicals since violent reactions can occur. Store in tightly closed containers in a cool, dark, well-ventilated area away from fire, sparks, and flame. Use non-sparking tools on containers. Ground and bond metal containers during transfer operations. | | | | |
| Other Precautions and Warnings | | | | |
| Containers may explode in fire or under conditions of extreme heat (do not store outdoors or in direct sunlight). Protect containers from physical damage. | | | | |
| SECTION VIII - CONTROL MEASURES AND PERSONAL PROTECTIVE EQUIPMENT | | | | |
| Respiratory Protection (<i>specify type</i>) | | | | |
| Exposures above 200 ppm: MSHA/NIOSH-approved full-facepiece respirator with organic vapor cartridge. Greater protection is obtained from a self-contained breathing apparatus (SCBA) with full facepiece and pressure demand or other positive pressure mode. | | | | |
| Ventilation | | | | |

METHYL ETHYL KETONEC₄H₈O

CAS: 78-93-3

**IDENTIFICATION AND TYPICAL USES**

Methyl ethyl ketone is a colorless liquid with a sweet mint or acetone-like odor. It is used as an industrial solvent, in the manufacture of smokeless powder and colorless synthetic resins, and as a surface coating. It is also used in the production of plastics, textiles, cements and adhesives, artificial leather, cosmetics, lubricating oils, pharmaceuticals, cleaning fluids, paint removers, and paints.

RISK ASSESSMENT: HEALTH**General Assessment**

Methyl ethyl ketone is moderately toxic to humans by *inhalation* and *absorption*. Skin or eye contact can also cause surface tissue damage and inflammation. There are no reports in the references to indicate that ingestion is a likely exposure route. The references contain no information on the carcinogenic or mutagenic properties of methyl ethyl ketone. However, it is suggested that it be treated as a suspected teratogen. Overexposure to this compound is not common. Its irritating properties and penetrating odor are usually present at levels low enough to serve as a warning to personnel.

Inhalation of methyl ethyl ketone causes irritation of the mucosa of the respiratory tract leading to respiratory depression with symptoms of gasping, choking, and dyspnea. Exposure to higher concentrations can cause depression of the central nervous system (CNS) with symptoms of headache, lachrymation, somnolence, decreased breathing, dizziness, fainting, blurred vision, tremor, parasthesia (numbness or tingling in the extremities), coma, and possibly death (rare but possible). If the liquid should be aspirated (during vomiting, for example), it can lead to chemical pneumonitis.

Skin contact with the liquid or vapor can lead to chemical dermatitis and localized paresthesia with symptoms of prickling or tingling with no apparent stimulus and associated sensory nerve damage. Methyl ethyl ketone can pass relatively quickly through intact skin to cause toxic systemic effects. When combined with other exposure routes, such as inhalation, the compound effects can be dangerous. Eye contact causes irritation with lachrymation and, in prolonged contact, may lead to ocular pain, corneal damage, and possible loss of vision.

Although ingestion is unlikely in the occupational setting, it can cause irritation of the mouth, sore throat, coughing, salivation, nausea, and vomiting.

☠ Acute Health Effects

The following acute (short-term) health effects may occur immediately or shortly after exposure to methyl ethyl ketone:

- Skin:** Irritation, dermatitis, and possible localized paresthesia.
- Eye:** Irritation with pain and inflammation that can lead to corneal damage and possible loss of vision.
- Lung:** Irritation causing coughing and/or shortness of breath. Higher exposures can cause dizziness, headache, and, possibly, coma and death.
- CNS:** A mild to moderate narcotic compound producing neurotoxicity as it is partially metabolized to methanol.

☪ Chronic Health Effects

The following chronic (long-term) health effects may occur at some time after exposure to methyl ethyl ketone and can last for months or even years:

Cancer Hazards: According to information presented in the references, methyl ethyl ketone has not been

adequately tested for its ability to cause cancer in laboratory test animals.

Reproduction: It has been suggested that this chemical be treated as a potential teratogen since it has been shown to adversely affect fetal development in limited experimental animal studies.

Other Chronic Effects: Studies with methyl ethyl ketone have shown that long-term skin exposure may produce dermatitis. However, unlike other ketones, methyl ethyl ketone is not considered a sensitizer. Also, methyl ethyl ketone has not been adequately tested to determine whether brain or other nerve damage could occur with repeated exposure. However, many solvents and other petroleum-based chemicals have been shown to cause such damage. Symptoms may include reduced memory and concentration, personality changes (withdrawal, irritability) fatigue, sleep disturbances, reduced concentration, and/or effects on nerves supplying internal organs (autonomic nerves) or the nerves to the arms and legs (weakness, tingling).

🔹 **Recommended Risk-Reduction Measures**

Personnel should avoid direct contact with methyl ethyl ketone. Unless a less toxic chemical can be substituted for a hazardous substance, *engineering controls* are the most effective method of reducing exposures. The best protection is to enclose operations and/or provide local exhaust ventilation at the site of chemical release. Because of its low flash point, maximum explosion-proof ventilation systems should be considered. While not always operationally feasible, isolating operations can also reduce exposure. Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with methyl ethyl ketone. For exposures to the PEL (200 ppm), use a NIOSH-approved, full facepiece organic vapor respirator. For higher or prolonged exposures, or when exposure levels are unknown (as in an emergency) a self-contained breathing apparatus (SCBA) with full facepiece operated in pressure demand mode, or a supplied-air respirator operated in continuous flow mode are the recommended respiratory protection methods of choice. If a full facepiece is not available, then chemical goggles should be worn to protect the eyes. Whenever a chemical splash hazard exists, a face shield and a rubber apron should be worn. To prevent hand and skin exposures, butyl rubber gloves should be used. Glove manufacturers should be contacted and permeation studies obtained *before* final glove selections are made.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with or around methyl ethyl ketone.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where methyl ethyl ketone is used or stored.

If symptoms develop or overexposure is suspected, the following medical tests may be helpful:

- ☑ Skin testing by a qualified allergist with special testing and careful evaluation of exposure history (may help diagnose allergy).
- ☑ Neurological evaluation of the central nervous system.

Other methods to reduce exposure include:

- ☑ Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. Explosion-proof design is recommended. If local exhaust ventilation or enclosure is not used, respiratory protection should be mandatory.
- ☑ Always ensure that proper protective clothing is worn when using chemical substances.
- ☑ Wash thoroughly immediately after exposure to methyl ethyl ketone and at the end of the work shift or before eating, drinking, or smoking. Never wear clothes contaminated with methyl ethyl ketone home.
- ☑ Hazard warning information should be posted in the work area. As part of an on-going education and training program, all information on the health and safety hazards of methyl ethyl ketone should be communicated to all exposed workers.

RISK ASSESSMENT: ENVIRONMENT

General Assessment

The environment is at risk of exposure during transportation, storage, disposal, or destruction of methyl ethyl ketone. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance. Accidental spills, large or small, can result in fire, explosion, and possible contamination of the surrounding environmental mediums (water, soil, and air).

Methyl ethyl ketone is considered a Class 1B flammable liquid (per OSHA 29 CFR 1910.106). Its

low flash point and relatively low boiling point make this chemical an extremely dangerous fire and explosion hazard. It can react with strong oxidizers and acids to cause a serious fire and explosion hazard. When involved in a fire, it can release acrid and irritating oxides of carbon. A boiling liquid expanding vapor explosion (BLEVE) is also a possibility. These characteristics require special consideration during any emergency involving a leak or spill of methyl ethyl ketone.

The proper disposal/destruction method for methyl ethyl ketone is to burn it in a chemical incinerator equipped with an afterburner and air scrubber.

Methyl ethyl ketone can enter the environment through manufacturing, unchecked discharge into effluents from industrial or municipal waste treatment plants, and through spills.

☠ *Acute Ecological Effects*

Acute (short-term) toxic effects may include the death of animals, birds, or fish, and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to methyl ethyl ketone. This chemical has a slight acute toxicity to aquatic life. No data are available on the short-term effects of methyl ethyl ketone on plants, birds, or land animals.

🕒 *Chronic Ecological Effects*

Chronic (long-term) toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals. Methyl ethyl ketone has slight chronic toxicity in aquatic life. No data are available to evaluate the long-term effects of methyl ethyl ketone to plants, birds, or land animals.

💧 *Water Solubility*

Methyl ethyl ketone is highly soluble in water. Concentrations of 1000 milligrams and more will mix with a liter of water.

🕒 *Persistence in the Environment*

Methyl ethyl ketone is slightly persistent in water, with a half-life of between 2 to 20 days. The half-life of a pollutant is the amount of time it takes for one half of the chemical to be degraded. Approximately 59% of methyl ethyl ketone will eventually end up in the air; the rest will end up in the water.

🐟 *Bioaccumulation in Aquatic Organisms*

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans.

The concentration of methyl ethyl ketone found in fish tissues is expected to be about the same as the average concentration of methyl ethyl ketone in water from which the fish was taken.

🔧 *Recommended Risk-Reduction Measures*

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in a leak or spill to the environment. The correct use of DOT labeling (per the MSDS) on all containers, trucks, and rail cars will enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of methyl ethyl ketone should be segregated from incompatible chemicals to minimize the risk of cross-contamination or contact. Buildings designated for storage should be equipped with appropriate fire protection systems (alarms, sprinklers, emergency lighting, portable extinguishers). Maximum explosion-proof design of ventilation systems is recommended.

If a spill or leak to the environment has occurred, fire department, emergency response, and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those trained in proper spill containment procedures. Contaminated soils should be removed for incineration and replaced with clean soil. If methyl ethyl ketone should contact the water table, aquifer, or navigable waterway, time is of the essence. It is highly soluble in water and, therefore, total containment and remediation may not be possible. When such spills occur, the local and/or state emergency response authorities may require notification. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of methyl ethyl ketone.

If methyl ethyl ketone is spilled or leaked, the following specific steps are recommended:

- Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened for normal work.
- Remove all ignition sources.
- Ventilate area of spill or leak.

Risk Management for Hazardous Chemicals

- ☑ Absorb liquids in vermiculite, dry sand, earth, or a similar material and deposit in sealed containers for disposal. Use non-sparking tools!
- ☑ Keep methyl ethyl ketone out of a confined space, such as a sewer, because of the possibility of explosion (unless the sewer is designed to prevent the buildup of explosive concentrations).
- ☑ It may be necessary to dispose of methyl ethyl ketone as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS***General Assessment***

Accidents or mishaps involving methyl ethyl ketone can present a significant threat to business operations. The loss or damage of equipment or facilities can significantly affect fiscal viability. Lawsuits that may result from personnel injury, public exposures, and/or environmental contamination will also require a serious expenditure of resources. Media attention surrounding an injury, illness, or environmental damage can also result in a loss of profits and loss of current as well as future business prospects.

🕒 *Recommended Risk-Reduction Measures*

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures dealing with safety or emergency response. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

| Health Hazards | | | | |
| INHALATION: Highly corrosive to the skin, eyes, and mucosa. Causes choking, chest pain, dyspnea, lethargy, nausea, convulsions, tremors, pulmonary edema, liver injury, hypoxia, blood disorders, and death. | | | | |
| ABSORPTION: Will pass through unbroken skin to cause toxic systemic effects as noted above. Extremely corrosive to skin tissue causing chemical burns (2 nd and 3 rd degree) on short contact. Very injurious to the eyes, causing corneal damage and permanent blindness. | | | | |
| INGESTION: A poison by ingestion. Delayed gastrointestinal irritation. Systemic effects can occur. | | | | |
| Carcinogenicity Suspected Human Confirmed Animal | NTP Listed? No | IARC Cancer Review Group? No | OSHA Regulated? 29 CFR 1910.1000 Table Z-1 | Target Organs? CNS, skin, liver, eyes, CVS, blood, resp. system. |
| Medical Conditions Generally Aggravated by Exposure Existing deficiencies in CNS function, liver, kidneys, and the circulatory system may be aggravated. | | | | |
| Emergency and First-aid Procedures Eye contact: Flush immediately with water for 15 minutes (minimum) while holding upper and lower eyelids open. Seek medical attention. Skin contact: Remove all contaminated clothing. Immediately wash area with large amounts of water (15 minutes minimum). For inhalation: Remove the person from exposure. Provide respiratory assistance and CPR. Transfer to medical facility. Observe for 24-48 hours for lung effects (pulmonary edema). If swallowed: Call the poison control center. Give 1-2 glasses of water or milk to a conscious and alert person. Seek medical attention immediately. Never attempt to give anything by mouth to an unconscious or convulsing person. | | | | |
| SECTION VII - PRECAUTIONS FOR SAFE HANDLING AND USE | | | | |
| Steps to be Taken in Case Material is Released or Spilled Evacuate area and deny entry to those not involved in cleanup activities. Protective clothing is mandatory. Remove all sources of ignition. Ventilate area of spill. Dilute with water to less than 40% methyl hydrazine solution. Absorb liquids with vermiculite or sand. Deposit in sealed drum for disposal. | | | | |
| Preferred Waste Disposal Method Incineration in a chemical incinerator equipped with afterburner and scrubber. | | | | |
| Precautions to be Taken in Handling and Storage Store in tightly closed containers in a cool, dark, dry, well-ventilated area. Personnel should be trained on the hazardous properties of methyl hydrazine <i>prior</i> to working with the material. | | | | |
| Other Precautions and Warnings Containers should be protected from physical damage. Use extreme caution when handling this compound. Use explosion-proof electrical equipment in areas where this chemical is used or stored. | | | | |
| SECTION VIII - CONTROL MEASURES AND PERSONAL PROTECTIVE EQUIPMENT | | | | |
| Respiratory Protection (<i>specify type</i>) A carcinogenic agent. Exposure level is extremely low and difficult to monitor. For any exposures, use a supplied-air respirator set in positive pressure or continuous flow mode or a self-contained breathing apparatus (SCBA) with full facepiece operated in pressure demand or other positive pressure mode. | | | | |
| Ventilation Local exhaust or general mechanical systems recommended. | | | | |
| Protective Gloves Impervious Gloves | | Eye Protection Chemical Goggles or Face Mask | | Other Protective Clothing Full Protective Clothing or Suit |
| Work/Hygiene Practices Always wash hands thoroughly after using chemical; never bring food, drink, or smoking materials into vicinity of chemicals. | | | | |

METHYL HYDRAZINE

CAS: 60-34-4

**IDENTIFICATION AND TYPICAL USES**

Methyl hydrazine is a colorless, fuming, oily liquid with an ammonia or fish-like odor. It is used primarily as a propellant in rocket fuels. It is a powerful reducing agent, a solvent, and an intermediate in chemical synthesis.

RISK ASSESSMENT: HEALTH**General Assessment**

Methyl hydrazine is a suspected human and animal carcinogen. It is an experimental teratogen and human mutation data have also been reported. It is primarily toxic by *inhalation* and skin contact (*absorption*). Although an unlikely exposure route, it can also cause toxic and damaging effects by *ingestion*.

Inhalation will cause pulmonary irritation up to and including pulmonary edema (fluid buildup in the lungs), which is a medical emergency and can lead to death. Symptoms may be delayed up to 48 hours creating a false sense of security with regard to health exposure risk. Symptoms include choking, extreme chest pain, dyspnea (difficulty in breathing), lethargy, nausea, convulsions, tremors, liver injury, and hypoxia (reduced oxygen levels in the blood) leading to hemolytic anemia. Systemic intoxication, depression of the central nervous system (CNS), and delayed gastrointestinal irritation may also occur. Methyl hydrazine may cause damage to the liver and destruction of red blood cells.

Aside from its ability to pass through intact skin (absorption), methyl hydrazine is also extremely corrosive to skin tissue and can cause second and third degree burns on contact. Damage to the eyes and cornea can be severe causing partial or complete loss of vision. It is a powerful reducing agent which is corrosive to the eyes, skin, and mucous membranes. May

also cause skin sensitization as well as systemic poisoning.

Ingestion is very unusual since the vapors of this chemical are so irritating, personnel are not likely to get close enough to ingest it. However, should it be swallowed, there can be burning of the mouth, throat, and esophagus, followed by gastrointestinal irritation.

☠ Acute Health Effects

The following acute (short-term) health effects may occur immediately or shortly after exposure to methyl hydrazine:

Skin: Severe irritation and burning. Extremely corrosive to tissues. Skin absorption will occur causing toxic systemic effects.

Eye: Severe irritation and tissue damage up to and including loss of vision.

Lung: Irritation of the upper respiratory tract causing choking, coughing, dyspnea, and pulmonary irritation leading to pulmonary edema (fluid in the lungs), which can be fatal.

CNS: Dizziness, convulsions, tremors, nausea, headaches, possible injury to the nervous system.

CVS: It can interfere with the proper function of the circulatory system and lead to cardiovascular collapse and death.

☘ Chronic Health Effects

The following chronic (long-term) health effects may occur at some time after exposure to methyl hydrazine and can last for months or even years:

Cancer Hazards: According to the information presented in the references, methyl hydrazine has been shown to cause cancer in test animals. Its carcinogenicity in humans is expected to be at least equal to

that of animals. Human mutation data have been reported for this compound.

Reproductive Hazard: According to the information presented in the references, this chemical has been shown to cause teratogenic effects as well as adversely affect reproduction in test animals.

Other Chronic Effects: Repeated exposures can lead to hemolytic anemia and convulsions. Chronic exposures may lead to cancer and/or liver and kidney damage. There can also be chronic inflammation of the nasal, tracheal, and bronchial tissue resulting in chronic bronchitis. Repeated skin exposure can cause dermatitis with a characteristic rash.

🕒 Recommended Risk-Reduction Measures

Methyl hydrazine is listed by the ACGIH as a confirmed animal carcinogen and a suspected human carcinogen. Unless a less toxic chemical can be substituted for a hazardous substance, *engineering controls* are the most effective method of reducing exposures. The best protection is to enclose operations and/or provide local explosion-proof exhaust ventilation at the site of chemical release. While not always operationally feasible, isolating operations can also reduce exposure.

Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around methyl hydrazine. The exposure level is extremely low (0.2 ppm) and difficult to detect and monitor. For any detectable exposures to a suspected carcinogenic agent, use a supplied-air respirator set in positive pressure or continuous flow mode, or use a self-contained breathing apparatus (SCBA) with full facepiece operated in pressure demand or other positive pressure mode. If a full facepiece is not available, then chemical goggles should be worn to protect the eyes. Whenever an eye or face contact hazard exists, a face shield and apron should be worn. To prevent hand and skin exposures, impervious gloves should be used. Glove manufacturers should be contacted and permeation studies obtained *before* final glove selection has been made.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques as well as the exposure control measures that will be practiced whenever personnel are to work with or around methyl hydrazine.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard

Communication), prior to the first assignment in an area where methyl hydrazine is used or stored. Before beginning employment and at regular intervals thereafter (e.g. annually), the following medical tests are recommended:

- ☑ Lung function tests (establish a baseline).
- ☑ Complete blood count (CBC).
- ☑ Examination of the nervous system.

If symptoms develop or overexposure is suspected, the following medical tests may be useful:

- ☑ Lung function tests.
- ☑ Liver and kidney function tests.
- ☑ Consider chest X-ray following acute overexposure (may be negative if taken immediately after exposure due to delayed onset of pulmonary edema).
- ☑ Evaluation by a qualified allergist with careful consideration of exposure history and special tests (may help diagnose allergy).

Any evaluation should include a careful medical history of past and present symptoms with an examination. However, medical tests that evaluate existing damage are not a substitute for controlling exposure. Since smoking can cause heart disease, emphysema, and numerous other respiratory disorders, smokers may be affected more rapidly than non-smokers under the same exposure conditions. Also, because alcohol consumption can cause liver damage, drinking alcohol can increase the potential for liver damage caused by exposure to methyl hydrazine. Prudent risk assessment and management requires careful consideration of *all* possible risk factors that may be causing the appearance of symptoms in exposed workers.

Other methods to reduce exposure include:

- ☑ Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not used, respiratory protection should be mandatory.
- ☑ Always ensure that proper protective clothing is worn when using chemical substances.
- ☑ Wash thoroughly immediately after exposure to methyl hydrazine and at the end of the work shift or before eating, drinking, or smoking.
- ☑ Hazard warning information must be posted in the work area. It is recommended that a regulated, controlled work area should be established wherever this chemical is used, handled, or

stored. In addition, as part of an on-going education and training program, all information on the health and safety hazards of methyl hydrazine should be communicated to all potentially exposed workers.

- ☑ Eye wash stations should be provided in work areas. If the potential for whole body exposure exists, then safety showers should also be provided in the immediately area.
- ☑ Specific engineering controls are recommended for a similar chemical by NIOSH in Publication Number 78-172 (*Occupational Exposure to Hydrazine*).

RISK ASSESSMENT: ENVIRONMENT

General Assessment

The environment is at risk of exposure during intended use, transportation, storage, disposal, or destruction of methyl hydrazine. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance. Accidental spills, large or small, can result in fire, explosion, and possible contamination of the surrounding environmental mediums (water, soil, and air).

Methyl hydrazine should always be handled with extreme caution. It is a Class 1B flammable liquid (per OSHA 29 CFR 1910.106). Its relatively low flash point and boiling point make this chemical a dangerous fire and explosion hazard. Its vapors form explosive mixtures in air over a wide range of concentrations in air and can easily ignite on exposure to air. It is highly reactive with a number of substances, especially oxidizers and oxidizing agents. It can also be quickly absorbed into porous materials such as wood and cloth. Its viscosity will make it difficult to remove from such materials. It attacks proteins such as leather and can remain in products such as belts and shoes for a long period of time. These characteristics require special consideration during any emergency situation involving a leak or spill of methyl hydrazine.

Methyl hydrazine can enter the environment through industrial discharges or through spills.

☠ *Acute Ecological Effects*

Acute (short-term) toxic effects may include the death of animals, birds, or fish and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to methyl hydrazine.

This chemical has high acute toxicity to aquatic life. Insufficient data are available to evaluate or predict the short-term effects of methyl hydrazine to plant, birds, or land animals.

☀ *Chronic Ecological Effects*

Chronic toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals. Methyl hydrazine has high chronic toxicity to aquatic life. Insufficient data are available to evaluate or predict the long-term effects of methyl hydrazine to plants, birds, or land animals.

💧 *Water Solubility*

Methyl hydrazine is highly soluble in water. Concentrations of 1000 milligrams and more will mix with a liter of water.

⌚ *Persistence in the Environment*

Methyl hydrazine is slightly persistent in water, with a half-life of less than 2 days. The half-life of a pollutant is the amount of time it takes for one half of the chemical to be degraded. Approximately 96.4% of methyl hydrazine will eventually end up in water; the rest will end up in the air.

🌊 *Bioaccumulation in Aquatic Organisms*

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans.

The concentration of methyl hydrazine found in fish tissues is expected to be about the same as the average concentration of methyl hydrazine found in the water from which the fish was taken.

🛡️ *Recommended Risk-Reduction Measures*

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in a leak or spill to the environment. The correct use of DOT labeling (per the MSDS) on all containers, trucks, and rail cars will enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of methyl hydrazine should be segregated from other chemicals, especially oxidizers, to mini-

mize the risk of cross-contamination or contact. Storage buildings should be equipped with proper fire protection and prevention equipment and explosion-proof electrical components and equipment. Bulk storage of methyl hydrazine is not recommended. Methyl hydrazine is hypergolic (ignites explosively) with incompatible materials such as oxidizers.

If a spill or leak to the environment has occurred, fire department, emergency response and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those trained in proper spill containment procedures and the health hazards associated with carcinogenic materials. Contaminated soils should be removed for incineration and replaced with clean soil. Use non-sparking tools. If methyl hydrazine should contact the water table, aquifer, or navigable waterway, remediation activities should be prompt to ensure protection of aquatic sediments. It is highly soluble in water and total containment and remediation may not be possible. When such spills occur, the local and/or state emergency response authorities must be notified. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of methyl hydrazine. Burning methyl hydrazine in a chemical incinerator equipped with an afterburner and an air scrubber is an acceptable disposal method.

If methyl hydrazine is spilled or leaked, the following specific steps are recommended:

- ☑ Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened for normal work.
- ☑ Ventilate area and remove all ignition sources.
- ☑ Absorb liquids in vermiculite or sand and place in a sealed drums for disposal.
- ☑ It may be necessary to dispose of methyl hydrazine as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving methyl hydrazine can present a significant threat to business operations. The loss or damage of equipment or facilities can significantly affect fiscal viability. Lawsuits that may result from personnel injury/death, public exposures,

and/or environmental contamination will also require a serious expenditure of resources. Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business.

Always remember that anytime the term "carcinogen," "cancer," or "reproductive hazard" are used, public emotion, hysteria, and ignorance can run equally high. This should be considered during the development of any public relations policies.

Recommended Risk-Reduction Measures

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures dealing with safety or emergency response. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

| Emergency and First-aid Procedures <u>Eye contact:</u> Do not allow victim to keep eyes shut. Flush immediately with water for 15 minutes minimum; seek medical attention. <u>Skin contact:</u> Remove all contaminated clothing. Immediately wash area with flooding amounts of soap and water. Seek medical attention immediately. For <u>inhalation:</u> Remove the person from exposure. Provide respiratory assistance and CPR. Observe for 24 - 48 hours for lung effects (pulmonary edema). Transfer to medical facility. If <u>swallowed:</u> Seek medical attention immediately. Never give an unconscious or convulsing person anything by mouth. | | | | |
| SECTION VII - PRECAUTIONS FOR SAFE HANDLING AND USE | | | | |
| Steps to be Taken in Case Material is Released or Spilled Remove all ignition sources, wear SCBA respiratory protection. Restrict those not wearing protective equipment who are not involved in cleanup from entering area. Absorb with vermiculite and place in sealed container. Damp mop residue. Flush residues with water (keep away from sewers). | | | | |
| Preferred Waste Disposal Method Burn in chemical incinerator equipped with an afterburner and scrubber. | | | | |
| Precautions to be Taken in Handling and Storage Store in tightly closed containers in cool, well-ventilated location. Keep away from sources of heat. | | | | |
| Other Precautions and Warnings Personnel must be trained on the hazards of working with methyl iodide <i>before</i> being assigned to areas where this chemical is used or stored. Empty cylinders contain residue; handle with care. | | | | |
| SECTION VIII - CONTROL MEASURES AND PERSONAL PROTECTIVE EQUIPMENT | | | | |
| Respiratory Protection (<i>specify type</i>) Possible human carcinogen. For best protection, use a supplied-air respirator with full facepiece or a self-contained breathing apparatus (SCBA) with full facepiece operated in positive pressure mode. | | | | |
| Ventilation Local exhaust (preferred) at site of chemical work or general ventilation. | | | | |
| Protective Gloves Impervious Rubber Gloves | | Eye Protection Chemical Goggles or Face Mask | Other Protective Clothing Protective Apron if Splash is Likely | |
| Work/Hygiene Practices Always wash hands thoroughly after using chemical; never bring food, drink, or smoking materials into vicinity of chemicals. | | | | |

METHYL IODIDECH₃I

CAS: 74-88-4

**IDENTIFICATION AND TYPICAL USES**

Methyl iodide is a colorless liquid that can turn yellow, brown, or red upon exposure to light, heat, or moisture. It has a sweet, pungent, ether-like odor. It is used primarily in organic synthesis, in microscopy, and in testing for pyridine.

RISK ASSESSMENT: HEALTH**General Assessment**

Methyl iodide is moderately toxic by *inhalation*. The liquid is also known to pass through the skin (*absorption*) to cause toxic systemic effects, and it is considered a human poison by *ingestion*. Methyl iodide is known to cause lung cancer in test animals and this effect is suspected to occur in humans as well. Human mutation data have been reported. It is a strong narcotic and anesthetic. The systemic effects of overexposure can be seen in the central nervous system. It is more toxic than methyl bromide and is considered to be at least ten times as toxic as carbon tetrachloride.

Inhalation is irritating to the eyes, nose, and mucosa of the respiratory tract. Symptoms include nausea, vomiting, diarrhea, ataxia, drowsiness, slurred speech, visual disturbances, and tremor. Irritation to lung tissues can lead to a dangerous buildup of fluids in the lungs (pulmonary edema), which is a medical emergency and can be fatal. Symptoms may be delayed up to 48 hours creating a false sense of security with regard to health risk. There can be coma and death following exposures to high concentrations.

Skin contact can produce severe localized irritation, burns, de-fatting of the surface leading to possible cracking, drying, and secondary infections. Absorption will occur rapidly causing an increase in tox-

icity. If coupled with inhalation, the systemic effects can be quite severe. Eye contact will also cause irritation and, if not removed immediately, possible damage to vision.

Ingestion can result in gastrointestinal irritation and may lead to systemic symptoms similar to that of inhalation.

☠ Acute Health Effects

The following acute (short-term) health effects may occur immediately or shortly after exposure to methyl iodide:

- Skin:** Irritation with potential for redness, pain, burns, and tissue damage.
- Eye:** Irritation and smarting of the conjunctiva. Can cause tearing, redness, pain, burns, and distortion to vision.
- Lung:** Irritation of the mucous membranes of the nose, throat, and respiratory tract causing possible ulceration, coughing, chest pains, difficulty breathing, and pulmonary edema.
- CNS:** Depression with headaches, lightheadedness, dizziness, nausea, vomiting, diarrhea, narcotic and anesthetic effects.

☘ Chronic Health Effects

The following chronic (long-term) health effects may occur at some time after exposure to methyl iodide and can last for months or even years:

Cancer Hazards: According to the references, methyl iodide is a confirmed animal carcinogen and several agencies consider methyl iodide to be a potential or suspect human carcinogen. These include the IARC (International Association for Research on Cancer),

the NTP (National Toxicology Program), and the ACGIH (American Conference of Governmental Industrial Hygienists). It has caused cancer of the lung in animals. Human mutation data have also been reported.

Reproductive Hazard: According to information presented in the references, methyl iodide has not been adequately tested for its ability to adversely affect reproduction.

Other Chronic Effects: Long-term exposure may damage the central nervous system, leading to disorientation and psychotic behavior. Repeated skin exposure can cause thickening and cracking of the skin.

🕒 **Recommended Risk-Reduction Measures**

Personnel should avoid direct contact with methyl iodide. It is a highly toxic, known cancer-causing agent. There may be no safe exposure level to methyl iodide. Occupational poisoning occurs most commonly by inhalation and skin absorption. If a less toxic material or compound cannot be substituted for methyl iodide, then *engineering controls* are the most effective method of reducing exposures. The best protection is to enclose operations and/or provide local exhaust ventilation at the site of methyl iodide release. While not always operationally feasible, isolating operations can also reduce exposure. Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around methyl iodide. Caution should be exercised when selecting respiratory protection since it is not known if exposure to methyl iodide will cause cancer in humans. A conservative approach to protection against exposure to a carcinogenic material may be prudent. For the best protection against a *possible carcinogen*, especially when the concentration is unknown, use a supplied-air respirator with full facepiece and mask operated in positive pressure mode or a self-contained breathing apparatus (SCBA) with full facepiece operated in pressure demand. If a full facepiece is not available, then chemical goggles should be worn to protect the eyes. A face shield should also be considered. To prevent hand and skin exposures, impervious rubber gloves should be used. Glove manufacturers should be contacted and permeation studies obtained *before* final glove selections have been made.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with methyl iodide.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where methyl iodide is used or stored.

Before beginning employment with methyl iodide and at regular intervals thereafter (e.g., annually), the following medical tests are recommended:

Lung function tests (establish baseline).

If symptoms develop or overexposure is suspected, the following tests should be considered:

Consider urine test for iodine.

Consider chest X-ray after acute overexposure (may be negative if taken immediately after exposure due to delayed onset of pulmonary edema).

Lung function tests (compare to baseline).

Any evaluation should include a careful history of past and present symptoms with an examination. Medical tests that simply look for existing damage are not a substitute for controlling exposures. Also, since smoking can cause heart disease, lung cancer, emphysema, and other respiratory problems, smokers may be affected more rapidly and with more pronounced symptoms than non-smokers. Prudent risk management requires careful consideration of *all* risk factors that might be causing the appearance of symptoms among workers.

Other methods to reduce exposure include:

Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not feasible, then respiratory protection should be provided and its use mandatory.

Always ensure that proper protective clothing is worn when using chemical substances.

Wash thoroughly immediately after exposure to methyl iodide and at the end of the work shift or before eating, drinking, or smoking.

Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of methyl iodide should be communicated to all potentially exposed workers.

Eye wash stations should be provided in the immediate work area for emergency use. If there is a possibility of skin exposure to methyl iodide,

emergency shower facilities should also be provided in the immediate work area.

- ☑ Workers whose clothing has been contaminated by methyl iodide should change into clean clothes before leaving work. Contaminated work clothing should be laundered only by individuals who have been informed of the hazards of exposure to methyl iodide.

RISK ASSESSMENT: ENVIRONMENT

General Assessment

The environment is at risk of exposure during transportation, storage, disposal, or destruction of methyl iodide. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance. Accidental spills, large or small, can result in contamination of the surrounding environmental mediums (water, soil, and air).

Methyl iodide is a non-combustible liquid. However, it can also react violently in the presence of strong oxidizers such as chlorine, chlorine dioxide, bromine, and nitrates, and permanganates. It is also likely to react on contact with silver chloride and sodium. Caution is always required in handling, storage, transportation, and disposal of methyl iodide. A phenomenon known as a boiling liquid expanding vapor explosion (BLEVE) can occur when tanks, containers, or rail cars containing methyl iodide are involved in a fire. The pressure that builds inside the container can explode violently and without much warning. Emergency responders should, therefore, be made aware of the presence of methyl iodide at any emergency response situation.

Methyl iodide can enter the environment from industrial effluents and from spills.

☠ *Acute Ecological Effects*

Acute (short-term) toxic effects may include the death of animals, birds, or fish and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to methyl iodide.

Methyl iodide has slight acute toxicity to aquatic life. Insufficient data are available to evaluate the short-term effects of methyl iodide on aquatic life, birds, or land animals.

🌱 *Chronic Ecological Effects*

Chronic (long-term) toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals.

Methyl iodide has slight chronic toxicity to aquatic life. Insufficient data are available to evaluate the long-term effects of methyl iodide to plants, birds, or terrestrial animals.

💧 *Water Solubility*

Methyl iodide is highly soluble in water. Concentrations of 1000 milligrams and more will mix with a liter of water.

⌚ *Persistence in the Environment*

Methyl iodide is non-persistent in water, with a half-life of less than 2 days. The half-life of a pollutant is the amount of time it takes for one half of the chemical to be degraded. About 99.5% of methyl iodide will eventually end up in air; the rest will end up in the water.

🐟 *Bioaccumulation in Aquatic Organisms*

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans.

The concentration of methyl iodide found in fish tissues is expected to be about the same as the average concentration of methyl iodide in the water from which the fish was taken.

🛡️ *Recommended Risk-Reduction Measures*

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in a leak or spill of methyl iodide into the environment. Labels on all containers, trucks, and rail cars must meet DOT requirements and accurately reflect their contents to enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of methyl iodide should be segregated from other chemicals and materials to minimize the risk of cross-contamination.

If a spill or leak to the environment has occurred, fire department, emergency response and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those

trained in proper spill containment procedures. Contaminated soils should be removed for incineration and replaced with clean soil. If methyl iodide should contact the water table, aquifer, or navigable waterway, time is of the essence. It is only highly and volatile soluble and, therefore, total remediation may not be possible. The local and/or state emergency response authorities must be notified. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of methyl iodide.

For disposal, methyl iodide may be burned in a chemical incinerator equipped with an afterburner and scrubber. If methyl iodide is spilled or leaked, the following specific steps are recommended:

- Restrict persons not wearing protective clothing from area of spill until cleanup is complete and area can be opened for normal work
- Absorb liquids in vermiculite, sand, earth, or similar material and deposit in sealed drum. Damp mop residue and collect for disposal. Direct cleanup activities away from sewers or waterways.
- Remove ignition sources and ventilate area of spill or leak.
- It may be necessary to dispose of methyl iodide as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving methyl iodide can present a serious threat to business operations. The loss or damage of equipment or facilities can significantly affect fiscal viability. Lawsuits that may result from personnel illness, injury/death, public exposures, and/or environmental contamination will require a serious expenditure of resources. Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business. Always remember that anytime the terms "cancer," "carcinogen," or "reproductive hazard" are used, public emotion, hysteria, and ignorance can run equally high. This must be carefully considered when developing any public relation policies.

Recommended Risk-Reduction Measures

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures for responding to chemical incidents. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

A solid stream of water may spread fire. If it can be done safely, move fire-exposed containers from area.

Unusual Fire and Explosion Hazards

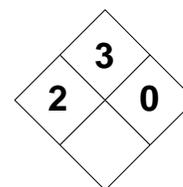

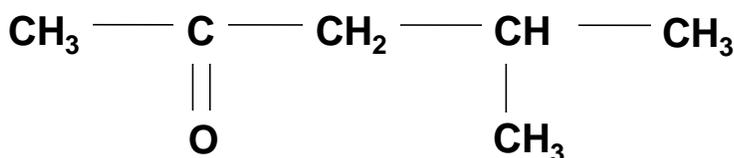

Containers may explode in fire due to the buildup of internal pressures. BLEVE (boiling liquid expanding vapor explosion) is possible. Immediately evacuate if rising sound is heard from venting device or a noticeable discoloration is observed on the sides of the tank or storage vessel.

SECTION V - REACTIVITY DATA

| | | | | |
|--|----------------------------|---|--|---|
| Stability | | Conditions to Avoid Normally stable. Do not allow methyl isobutyl ketone to come into contact with incompatible materials. Avoid contact with fire or high heat sources. Do not use in confined spaces. | | |
| Stable X | Unstable | Incompatibility (<i>materials to avoid</i>) Incompatible with strong oxidizers (chlorine, bromine, fluorine), potassium <i>tert</i>-butoxide, and can react vigorously with reducing materials. It forms explosive mixtures in air. | | |
| Hazardous Polymerization | | Conditions to Avoid Under normal conditions of temperature and pressure, hazardous polymerization of methyl isobutyl ketone is not expected to occur. | | |
| May Occur | Will Not Occur X | Hazardous Decomposition or By-products When heated to decomposition, methyl isobutyl ketone emits acrid, irritating smoke and fumes, including oxides of carbon. | | |
| SECTION VI - HEALTH HAZARD DATA | | | | |
| Primary Route(s) of Entry: | | Inhalation? X | Absorption (skin)? X | Ingestion? |
| Health Hazards INHALATION: Causes irritation to the eyes and mucosa. Symptoms include excitability, headache, loss of appetite, sore throat, visual disturbances, pale complexion, tiredness, nausea, and vomiting. High concentrations cause central nervous system depression with symptoms of intoxication, stupor, staggering, mental confusion, loss of consciousness, coma, and death. Animal studies suggest liver, brain, lung, and spleen injuries. ABSORPTION: Skin contact with liquid or vapor can result in irritation and may cause dermatitis and redness (erythema). Eye contact causes pain, irritation, and corneal damage, tearing. INGESTION: Unlikely. Symptoms of irritation, sore throat, nausea, coughing, salivation, vomiting. | | | | |
| Carcinogenicity Unknown Human Unknown Animal | NTP Listed? No | IARC Cancer Review Group? No | OSHA Regulated? 29 CFR 1910.1000 Table Z-1 | Target Organs? Respiratory system; skin; eyes; CNS. |
| Medical Conditions Generally Aggravated by Exposure Skin conditions (dermatitis) may be aggravated. | | | | |
| Emergency and First-aid Procedures Eye contact: Immediately flush with large amounts of water for 15 minutes (minimum), occasionally lifting eyelids. Skin contact: Remove all contaminated clothing. Immediately wash area with large amounts of soap and water. For inhalation: Remove the person from exposure. Provide respiratory assistance and CPR. Transfer promptly to medical facility. If swallowed: Seek medical attention. Give a conscious and alert victim several glasses of water and then induce vomiting with Ipecac syrup. | | | | |
| SECTION VII - PRECAUTIONS FOR SAFE HANDLING AND USE | | | | |
| Steps to be Taken in Case Material is Released or Spilled Remove all ignition sources. Restrict persons not wearing protective equipment from entering area of spill or leak until cleanup is complete. Ventilate area. Absorb liquid in dry sand or other material and deposit in sealed containers. Damp mop residue. Alert appropriate state or federal response agencies. | | | | |
| Preferred Waste Disposal Method Burn in a chemical incinerator equipped with an afterburner and scrubber. | | | | |
| Precautions to be Taken in Handling and Storage Do not store with incompatible chemicals since violent reactions can occur. Store in tightly closed containers in a cool, dark, well-ventilated area away from fire, sparks, and flame. Use non-sparking tools on containers. Ground and bond metal containers during transfer operations. | | | | |
| Other Precautions and Warnings Containers may explode in fire or under conditions of extreme heat. | | | | |
| SECTION VIII - CONTROL MEASURES AND PERSONAL PROTECTIVE EQUIPMENT | | | | |
| Respiratory Protection (<i>specify type</i>) Exposures above 50 ppm: MSHA/NIOSH-approved full-facepiece respirator with organic vapor cartridge. Greater protection is obtained from a self-contained breathing apparatus (SCBA) with full facepiece and pressure demand or other positive pressure mode. | | | | |
| Ventilation Local exhaust or general mechanical systems recommended. | | | | |
| Protective Gloves Impervious Materials | | Eye Protection Chemical Goggles and/or Face Mask | | Other Protective Clothing Protective Apron |
| Work/Hygiene Practices Always wash hands thoroughly after using chemical; never bring food, drink, or smoking materials into vicinity of chemicals. | | | | |

METHYL ISOBUTYL KETONE

CAS: 108-10-1

**IDENTIFICATION AND TYPICAL USES**

Methyl isobutyl ketone (MIBK) is a colorless liquid with a sweet, camphor-like odor. It is used as a solvent for gums, resins, nitrocellulose and cellulose ethers, paints, varnishes, lacquers, protective coatings, and various fats, oils, and waxes. It is also used in the manufacture of methyl amyl alcohol and antibiotics, as a synthetic flavoring agent, and in the plastic and petroleum industries.

RISK ASSESSMENT: HEALTH**General Assessment**

MIBK is mildly toxic to humans by *inhalation* and *absorption*. Skin or eye contact can also cause surface tissue damage and inflammation. It is a human poison by *ingestion*. The references contain no information on the carcinogenic or mutagenic properties of MIBK. However, it is suggested that it be treated as a suspected teratogen. Overexposure to this compound is not common. Its irritating properties and penetrating odor are usually present at levels low enough to serve as a warning to personnel.

Inhalation of MIBK causes irritation of the mucosa of the respiratory tract leading to respiratory depression with symptoms of gasping, choking, and dyspnea. Exposure to higher concentrations can cause depression of the central nervous system (CNS) with symptoms of excitability, headache, appetite loss, sore throat, visual disturbances, pale complexion, fatigue, nausea, and vomiting. Higher concentrations can lead to dizziness, intoxication, stupor, staggering gait, loss of coordination, mental confusion, coma, and death. There may also be liver, spleen, brain, and lung injuries.

Skin contact with the liquid can lead to chemical dermatitis, inflammation, redness, and rash. MIBK can pass relatively quickly through intact skin to cause toxic systemic effects. When combined with other

exposure routes, such as inhalation, the compound effects can be dangerous. Eye contact causes irritation with lachrymation and, in prolonged contact, may lead to ocular pain, corneal damage, and possible visual disturbances (blurred vision). Although ingestion is unlikely in the occupational setting, it can cause irritation of the mouth and throat with nausea and vomiting.

☠ Acute Health Effects

The following acute (short-term) health effects may occur immediately or shortly after exposure to MIBK:

- Skin: Irritation and dermatitis with possible localized rash and redness. Absorption is likely.
- Eye: Irritation with pain and inflammation that can lead to corneal damage and possible visual disturbances.
- Lung: Irritation causing coughing and/or shortness of breath. Higher exposures can cause dizziness, headache, and, possibly, coma and death.
- CNS: A mild to moderate narcotic compound producing neurotoxicity as it is partially metabolized to methanol.

☠* Chronic Health Effects

The following chronic (long-term) health effects may occur at some time after exposure to MIBK and can last for months or even years:

Cancer Hazards: According to information presented in the references, MIBK has not been adequately tested for its ability to cause cancer in laboratory test animals.

Reproduction: It has been suggested that this chemical be treated as a potential teratogen since it has been shown to adversely affect fetal development in experimental animal studies.

Other Chronic Effects: Studies with MIBK have shown that long-term skin exposure may produce dermatitis. Long-term exposure has caused fatty-degeneration of the liver, brain, lungs, and spleen in test animals. It is not known if human exposure to MIBK will have this effect. Also, MIBK has not been adequately tested to determine whether brain or other nerve damage could occur with repeated exposure. However, many solvents and other petroleum-based chemicals have been shown to cause such damage. Symptoms may include reduced memory and concentration, personality changes (withdrawal, irritability) fatigue, sleep disturbances, reduced concentration, and/or effects on nerves supplying internal organs (autonomic nerves) or the nerves to the arms and legs (weakness, tingling).

🔗 **Recommended Risk-Reduction Measures**

Personnel should avoid direct contact with MIBK. Unless a less toxic chemical can be substituted for a hazardous substance, *engineering controls* are the most effective method of reducing exposures. The best protection is to enclose operations and/or provide local exhaust ventilation at the site of chemical release. Because of its low flash point, maximum explosion-proof ventilation systems should be considered. While not always operationally feasible, isolating operations can also reduce exposure. Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with MIBK. For exposures to the PEL (50 ppm), use a NIOSH-approved, full facepiece organic vapor respirator. For higher or prolonged exposures, or when exposure levels are unknown (as in an emergency) a self-contained breathing apparatus (SCBA) with full facepiece operated in pressure demand mode, or a supplied-air respirator operated in continuous flow mode are the recommended respiratory protection methods of choice. If a full facepiece is not available, then chemical goggles should be worn to protect the eyes. Whenever a chemical splash hazard exists, a face shield and a rubber apron should be worn. To prevent hand and skin exposures, butyl rubber gloves should be used. Polyvinyl alcohol gloves have proven effective. However, glove manufacturers should be contacted and permeation studies obtained *before* final glove selections are made.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be prac-

ticed whenever personnel are to work with or around MIBK.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where MIBK is used or stored.

If symptoms develop or overexposure is suspected, the following medical tests may be helpful:

- ☑ Skin testing by a qualified allergist with special testing and careful evaluation of exposure history (may help diagnose allergy).
- ☑ Neurological evaluation of the central nervous system.
- ☑ Liver and kidney function tests.

Other methods to reduce exposure include:

- ☑ Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. Explosion-proof design is recommended. If local exhaust ventilation or enclosure is not used, respiratory protection should be mandatory.
- ☑ Always ensure that proper protective clothing is worn when using chemical substances.
- ☑ Wash thoroughly immediately after exposure to MIBK and at the end of the work shift or before eating, drinking, or smoking. Never wear clothes contaminated with MIBK home. Family members can be exposed.
- ☑ Hazard warning information should be posted in the work area. As part of an on-going education and training program, all information on the health and safety hazards of MIBK should be communicated to all exposed workers.

RISK ASSESSMENT: ENVIRONMENT

General Assessment

The environment is at risk of exposure during transportation, storage, disposal, or destruction of MIBK. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance. Accidental spills, large or small, can result in fire, explosion, and possible contamination of the surrounding environmental mediums (water, soil, and air).

MIBK is considered a Class 1B flammable liquid (per OSHA 29 CFR 1910.106). Its low flash point and relatively low boiling point make this chemical an ex-

tremely dangerous fire and explosion hazard. It can react with strong oxidizers and acids to cause a serious fire and explosion hazard. When involved in a fire, it can release acrid and irritating oxides of carbon. A boiling liquid expanding vapor explosion (BLEVE) is also a possibility. These characteristics require special consideration during any emergency involving a leak or spill of MIBK.

The proper disposal/destruction method for MIBK is to burn it in a chemical incinerator equipped with an afterburner and air scrubber.

MIBK can enter the environment through manufacturing, unchecked discharge into effluents from industrial or municipal waste treatment plants, and through spills.

☠ *Acute Ecological Effects*

Acute (short-term) toxic effects may include the death of animals, birds, or fish, and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to MIBK.

This chemical has a slight acute toxicity to aquatic life and high acute toxicity to birds. No data are available on the short-term effects of MIBK on plants or land animals.

🕒 *Chronic Ecological Effects*

Chronic (long-term) toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals.

MIBK has slight chronic toxicity in aquatic life. No data are available to evaluate the long-term effects of MIBK to plants, birds, or land animals.

💧 *Water Solubility*

MIBK is highly soluble in water. Concentrations of 1000 milligrams and more will mix with a liter of water.

🕒 *Persistence in the Environment*

MIBK is slightly persistent in water, with a half-life of between 2 to 20 days. The half-life of a pollutant is the amount of time it takes for one half of the chemical to be degraded. Approximately 61.5% of MIBK will eventually end up in the air; the rest will end up in the water. Accumulation of MIBK in aquatic or terrestrial sediments has not been demonstrated.

🐟 *Bioaccumulation in Aquatic Organisms*

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans.

The concentration of MIBK found in fish tissues is expected to be about the same as the average concentration of MIBK in water from which the fish was taken.

🛡️ *Recommended Risk-Reduction Measures*

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in a leak or spill to the environment. The correct use of DOT labeling (per the MSDS) on all containers, trucks, and rail cars will enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of MIBK should be segregated from incompatible chemicals to minimize the risk of cross-contamination or contact. Buildings designated for storage should be equipped with appropriate fire protection systems (alarms, sprinklers, emergency lighting, portable extinguishers). Maximum explosion-proof design of ventilation systems is recommended.

If a spill or leak to the environment has occurred, fire department, emergency response, and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those trained in proper spill containment procedures using non-sparking tools. Contaminated soils should be removed for incineration and replaced with clean soil. If MIBK should contact the water table, aquifer, or navigable waterway, time is of the essence. It is highly soluble in water and, therefore, total containment and remediation may not be possible. When such spills occur, the local and/or state emergency response authorities may require notification. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of MIBK.

If MIBK is spilled or leaked, the following specific steps are recommended:

- ☑ Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened for normal work.
- ☑ Remove all ignition sources.

- ☑ Ventilate area of spill or leak.
- ☑ Absorb liquids in vermiculite, dry sand, earth, or a similar material and deposit in sealed containers for disposal. Use non-sparking tools!
- ☑ Keep MIBK out of a confined space, such as a sewer, because of the possibility of explosion (unless the sewer is designed to prevent the buildup of explosive concentrations).
- ☑ It may be necessary to dispose of MIBK as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving MIBK can present a significant threat to business operations. The loss or damage of equipment or facilities can significantly affect fiscal viability. Lawsuits that may result from personnel injury, public exposures, and/or environmental contamination will also require a serious expenditure of resources. Media attention surrounding an injury, illness, or environmental damage can also result in a loss of profits and loss of current as well as future business prospects. Always remember that anytime the term "reproductive hazard" is used, public hysteria, emotion, and ignorance can run equally high. This must be carefully considered when adopting any public relations policies.

Recommended Risk-Reduction Measures

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures dealing with safety or emergency response. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

METHYL ISOCYANATECH₃NCO

CAS: 624-83-9

**IDENTIFICATION AND TYPICAL USES**

Methyl isocyanate appears as a clear, colorless liquid with a sharp, pungent odor. It is used primarily as an intermediate in the manufacture of pesticides and insecticides (including carbaryl), in organic synthesis, and in the production of plastics and polyurethane foams and insulation products.

RISK ASSESSMENT: HEALTH**General Assessment**

Methyl isocyanate is an extremely toxic and poisonous substance. It can enter the body through *inhalation* skin contact (*absorption*), and by *ingestion*. It will also cause adverse topical health effects on contact with the skin. There is no information on its carcinogenic capabilities in humans or animals. However, incidents of spontaneous abortions and fetal abnormalities have been reported following acute overexposures. Mutation data have also been reported.

Inhalation exposures to high concentrations of the vapor can be extremely irritating to the eyes, nose, throat, and mucosa of the respiratory tract. Blindness has been reported. Symptoms of exposure include wheezing, coughing, increased secretions (runny nose), dyspnea, sweating, difficulty in breathing, insomnia, painful respiration, and possible life-threatening pulmonary edema (fluid in the lungs). Development of pulmonary edema may be delayed up to 48 hours thereby creating a false sense of security with regard to health exposure risk. In severe cases, there may be some restriction of air movement and eventual respiratory failure (due to edema). Prolonged contact can lead to chronic bronchitis, asthma-like symptoms, permanent fibrosis, and allergic pulmonary sensitization.

Skin contact causes irritation and painful burning with skin blisters on prolonged contact. If the liquid should contact the eye directly, there may be irritation, inflammation of the eyelids and surrounding tissues,

conjunctivitis, and possible damage to the cornea. Ingestion causes unspecified gastrointestinal effects. Human data on exposure to methyl isocyanate are well documented as a result of an accidental release of the substance in Bhopal, India. This chemical presents a serious and life-threatening risk to human health.

☠ Acute Health Effects

The following acute (short-term) health effects may occur immediately or shortly after exposure to methyl isocyanate:

- Skin: Possible irritation with painful burning and blistering. Sensitization is possible.
- Eye: Moderate to severe irritation. There can be inflammation, irritation of the eyelids, photophobia, tearing, conjunctivitis, and blindness.
- Lung: Irritation of the nose, throat, and lungs following exposure. There can be a delayed but dangerous buildup of fluid in the lungs (pulmonary edema), which is a medical emergency.

☘ Chronic Health Effects

The following chronic (long-term) health effects may occur at some time after exposure to methyl isocyanate and can last for months or even years:

Cancer Hazards: There is insufficient information in the references on the carcinogenic properties of methyl isocyanate. However, mutation data have been reported and many scientists believe that such chemicals may pose a cancer risk in the long-term.

Reproductive Hazard: According to the data presented in the references, methyl isocyanate may cause spontaneous abortions or lead to the development of fetal abnormalities.

Other Chronic Effects: Long-term exposure to methyl isocyanate may lead to allergic sensitization of the respiratory system with initial symptoms of night

coughs and difficulty breathing and possible progression to asthmatic bronchitis. Repeated exposure may lead to permanent lung damage. Skin sensitization may occur on prolonged contact.

🕒 **Recommended Risk-Reduction Measures**

Personnel should avoid direct contact with methyl isocyanate. It is an extremely toxic and poisonous substance that must be handled with extreme care. If a less toxic chemical cannot be substituted for a hazardous substance, then *engineering controls* are the most effective method of reducing exposures.

The best protection is to enclose operations and/or provide local exhaust ventilation at the site of chemical release. While not always operationally feasible, isolating operations can also reduce exposure. Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around methyl isocyanate. The PEL for this chemical is extremely low (0.02 ppm) and difficult to monitor reliably under most operating or emergency conditions. A supplied-air respirator with a full facepiece operated in positive pressure mode or an MSHA/NIOSH-approved self-contained breathing apparatus (SCBA) with full facepiece operated in pressure demand or other positive pressure mode are the recommended respiratory protection methods of choice. In either case, if a full facepiece is not available, then chemical splash goggles should be worn to protect the eyes. Whenever a chemical splash hazard exists, a face shield and a protective apron should be worn. To prevent hand and skin exposures, impervious gloves should be used. Glove manufacturers should be contacted and permeation studies obtained before final glove selections are made.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with methyl isocyanate.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where methyl isocyanate is used or stored.

If symptoms develop or overexposure is suspected, the following medical tests are recommended:

- Lung function tests (establish baseline)

- Consider chest X-ray after acute over exposure (may be negative if taken immediately after exposure due to delayed onset of pulmonary edema).
- Evaluation by a qualified allergist with special testing and careful consideration of exposure history (may help diagnose allergy).

Also, since smoking can cause heart disease, emphysema, and other lung diseases, smokers exposed to methyl isocyanate may experience symptoms more quickly than non-smokers under the same conditions of exposure. Prudent risk management requires proper consideration of *all* possible exposure factors when evaluating workplace health hazard risk.

Other methods to reduce exposure include:

- Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not used, respiratory protection should be mandatory.
- Where possible, automatically transfer methyl isocyanate from drums or other storage containers to process containers.
- Always ensure that proper protective clothing is worn when using chemical substances and that personnel are trained on its use and care.
- Wash thoroughly immediately after exposure to methyl isocyanate and at the end of the work shift or before eating, drinking, or smoking.
- Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of methyl isocyanate should be communicated to all exposed and potentially exposed workers.

RISK ASSESSMENT: ENVIRONMENT

General Assessment

The environment is at risk of exposure during transportation, storage, disposal, or destruction of methyl isocyanate. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance. Accidental spills, large or small, can result in fire, explosion, and possible contamination of the surrounding environmental mediums (water, soil, and air).

Methyl isocyanate is considered a Class IB combustible liquid (per OSHA 29 CFR 1910.106). It can react vigorously with oxidizing agents, water, alcohols, strong bases, amines, alkalis, iron, tin, copper,

elastomers, alcohols, and glycols. In addition, pressure may build in closed containers. These characteristics require special consideration during any emergency situation involving a leak or spill of methyl isocyanate.

Methyl isocyanate may enter the environment primarily during the disposal of wastes from the chlorinated hydrocarbon industry.

☠ *Acute Ecological Effects*

Acute (short-term) toxic effects may include the death of animals, birds, or fish and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to methyl isocyanate.

Insufficient data are available to evaluate or predict the short-term effects of methyl isocyanate exposure to aquatic life, plants, birds, or land animals.

☞ *Chronic Ecological Effects*

Chronic (long-term) toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals.

Insufficient data are available to evaluate or predict the long-term effects of methyl isocyanate to aquatic life, plants, birds, or terrestrial animals.

💧 *Water Solubility*

Methyl isocyanate decomposes exothermically in water. It is, therefore, only slightly soluble in the aquatic environment. Concentrations of less than 1 to 100 milligrams will mix with a liter of water.

🕒 *Persistence in the Environment*

Methyl isocyanate is non-persistent in the aquatic environment, with a half-life of less than 2 days. The half-life of a pollutant is the amount of time it takes for one half of the chemical to be degraded. Because methyl isocyanate will react with water, it is not expected to accumulate in the environment.

🐟 *Bioaccumulation in Aquatic Organisms*

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the body tissues and, especially, in the internal organs of animals as well as humans.

Because methyl isocyanate will react with water, it is not expected to accumulate in aquatic organisms.

🔧 *Recommended Risk-Reduction Measures*

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in a leak or spill to the environment. The correct use of labeling on all containers, trucks, and rail cars will enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of methyl isocyanate should be segregated from incompatible chemicals to minimize the risk of cross-contamination or contact. Storage buildings or facilities should be equipped with proper fire protection equipment (sprinklers/extinguishers, alarms).

If a spill or leak to the environment has occurred, fire department, emergency response and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those trained in proper spill containment procedures. Contaminated soils should be removed for incineration and replaced with clean soil. If methyl isocyanate should contact the water table, aquifer, or navigable waterway, time is of the essence. Even though it is only slightly soluble in the aquatic environment, it will quickly decompose in water and, therefore, total containment and remediation will not be possible. When such spills occur, the local and/or state emergency response authorities must be notified. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of methyl isocyanate. The proper disposal method for methyl isocyanate is to burn it in a chemical incinerator equipped with an afterburner and an air scrubber.

If methyl isocyanate are spilled or leaked, the following specific response steps are recommended:

- ☑ Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened for normal work.
- ☑ Remove all ignition sources.
- ☑ Ventilate area of spill or leak.
- ☑ If liquid is spilled, absorb in vermiculite, dry sand, earth, or similar material and deposit in sealed containers. Use non-sparking tools.
- ☑ It may be necessary to dispose of methyl isocyanate as a hazardous waste. The responsible

state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving methyl isocyanate can present a significant threat to business operations. The loss or damage of equipment or facilities can significantly affect fiscal viability. Lawsuits that may result from personnel injury/death, public exposures, and/or environmental contamination will also require a serious expenditure of resources. Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business. Always remember that anytime the term "reproductive hazard" is used, public hysteria, emotion, and ignorance can run equally high. This is also particularly true with the mere mention of methyl isocyanate as people recall the tragedy of Bhopal, India. These facts must be carefully considered whenever developing or implementing public relations policies or procedures.

Recommended Risk-Reduction Measures

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures for responding to hazardous chemical incidents. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

SECTION I - GENERAL INFORMATION

| | | |
|---|--|---------------------------------|
| Characterization Aliphatic Ester | RCRA Number U162 | EPA Class Toxic Waste |
| DOT Proper Shipping Name Methyl methacrylate monomer, Inhibited | Chemical Abstract Service (CAS) Number 80-62-6 | |
| DOT Hazard Class and Label Requirements Flammable Liquid | DOT Emergency Guide Code 26 (Inhibited) | |
| DOT Identification Number UN 1247 | Chemical Formula CH₂=C(CH₃)COOCH₃ | |

Synonyms

Methyl methacrylate (inhibited); methacrylate monomer; methyl methacrylate monomer; methyl ester of methacrylic acid; methyl-2-methyl-2-propenoate.

SECTION II - HAZARDOUS INGREDIENTS AND IDENTITY INFORMATION

| Hazardous Components (specific identity) | OSHA Exposure Criteria | NIOSH Exposure Criteria | Immediately Dangerous to Life and Health (IDLH) | ACGIH Exposure Criteria |
|--|---|--|---|---|
| Methyl methacrylate (derivation: From acetone cyanohydrin, methanol, and dilute sulfuric acid; by oxidation of tertbutyl alcohol to methacrolein and then to methacrylic acid, followed by reaction with methanol). 1 ppm = 4.16 mg/m³ | PEL: 100 ppm 410 mg/m³ STEL: Not Determined | REL: 100 ppm 4105 mg/m³ STEL: Not Determined | 1000 ppm | TLV: 100 ppm 410 mg/m³ STEL: Not Determined |

SECTION III - PHYSICAL AND CHEMICAL CHARACTERISTICS

| | |
|--|--|
| Boiling Point 214°F (101°C) | Specific Gravity (H ₂ O = 1) 0.94 |
| Vapor Pressure (mm Hg) 29 at 68°F (20°C) | Molecular Weight 100.1 |
| Vapor Density (Air = 1) 3.45 | Melting Point -54°F (-48°C) |

Solubility

Slightly soluble in water (1.5%). Soluble in most organic solvents.

Appearance and Odor

Clear, colorless liquid with a sharp, acrid, fruity odor. Odor Threshold = 0.083 ppm.

SECTION IV - FIRE AND EXPLOSION HAZARD DATA

| | | |
|--|---|--|
| Flash Point (method used) 50°F (-3°C) opened cup | Explosive Limits in Air % by Volume LEL: 1.78% UEL: 8.2% | |
| NFPA Classification Class IB Flammable Liquid | Autoignition Temperature 790°F (421°C) | |

Extinguishing Media

Dry chemical, alcohol foam, or carbon dioxide. Use blanketing effect with foam to smother large fires.

Special Fire Fighting Procedures

Poisonous gases are produced in fire. Wear full protective clothing and (SCBA). Continue to cool containers with water after fire is out. Move containers from fire area if it can be done without risk.

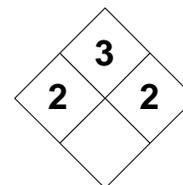

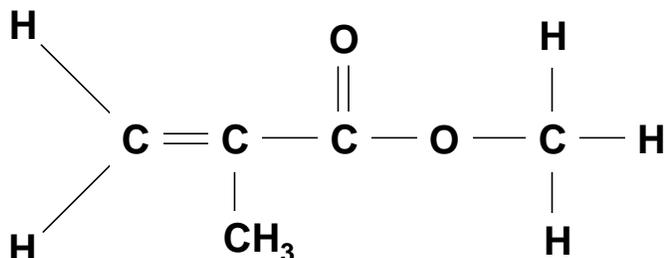

Unusual Fire and Explosion Hazards

Evacuate 2500 feet radius if fire becomes uncontrollable or container is exposed to direct flame. Vapors are heavier than air and may travel a distance to ignition source to flashback. Heat and/or an insufficient concentration of inhibitor can cause violent polymerization with the rupture of container.

| SECTION V - REACTIVITY DATA | | | | |
|---|--|--|--|--|
| Stability | | Conditions to Avoid Methyl methacrylate is kept stable under normal conditions of storage and operation with an inhibitor. Avoid contact with incompatible materials. Keep away from heat, flame, and other sources of ignition. | | |
| Stable X | Unstable | Incompatibility (materials to avoid) Reacts violently in contact with oxidizers (peroxides, nitrates, perchlorates, chlorates, permanganates) polymerizers, strong alkalis (sodium hydroxide, potassium hydroxide), moisture, chlorosulfonic acid. | | |
| Hazardous Polymerization | | Conditions to Avoid Explosive polymerization can occur if inhibitor levels become too low or when exposed to heat, light, oxidizers, and peroxides. | | |
| May Occur X | Will Not Occur | Hazardous Decomposition or By-products When heated to decomposition, methyl methacrylate emits acrid and irritating fumes, including oxides of carbon (monoxide and dioxide). | | |
| SECTION VI - HEALTH HAZARD DATA | | | | |
| Primary Route(s) of Entry: | | Inhalation? X | Absorption (skin)? | Ingestion? X |
| Health Hazards INHALATION: Severe irritation to the eyes, nose, throat, and respiratory system. Exposure can cause drowsiness, headache, vomiting, and nausea. Severe exposures may cause depression of the central nervous system with anorexia, irritability, and narcosis. There also may be dyspnea, cyanosis, convulsions, lachrymation, coughing, fatigue, and wheezing. SKIN & EYES: Skin and eye irritation. Eye tissue damage may occur on contact. Parasthesia (tingling sensation on the skin) may occur on prolonged or repeated contact. INGESTION: Severe local irritation of the gastrointestinal tract with irritation of the lips, mouth, throat, painful swallowing, abdominal pain and cramps, nausea, vomiting, and diarrhea. | | | | |
| Carcinogenicity Unknown Human Questioned Animal | NTP Listed? No | IARC Cancer Review Group? Group 3 | OSHA Regulated? 29 CFR 1910.1000 Table Z-1 | Target Organs? Respiratory system; skin; eyes. |
| Medical Conditions Generally Aggravated by Exposure None reported. | | | | |
| Emergency and First-aid Procedures Eye contact: Flush immediately with water for 15 minutes (minimum); seek medical attention. Skin contact: Remove all contaminated clothing. Immediately wash area with large amounts of soap and water. Seek medical assistance. For inhalation: Remove the person from exposure. Provide respiratory assistance and CPR. Transfer to medical facility. If swallowed: Contact poison control center. Give 1 to 2 glasses of water; induce vomiting until vomitus is clear. Seek medical attention immediately. | | | | |
| SECTION VII - PRECAUTIONS FOR SAFE HANDLING AND USE | | | | |
| Steps to be Taken in Case Material is Released or Spilled Contain spills using absorbent material (vermiculite or other). Ventilate area of spill and remove ignition sources. Have extinguishing agent available. Use non-sparking tools. Store materials in DOT-approved containers. Restrict those not involved in cleanup from entering area. | | | | |
| Preferred Waste Disposal Method Incineration in chemical incinerator equipped with scrubber and afterburner. | | | | |
| Precautions to be Taken in Handling and Storage Store in tightly closed containers in a cool, dark, well-ventilated area. Protect containers from physical damage. Keep heat, fire, and flame away. Outside building storage is recommended. | | | | |
| Other Precautions and Warnings Bulk storage of methyl methacrylate is not recommended. Ground and bond all metal containers. | | | | |
| SECTION VIII - CONTROL MEASURES AND PERSONAL PROTECTIVE EQUIPMENT | | | | |
| Respiratory Protection (specify type) Carcinogenic properties unknown. Use a supplied-air respirator or a self-contained breathing apparatus (SCBA) with full facepiece operated in positive pressure mode for the best protection. | | | | |
| Ventilation Local exhaust or general mechanical systems recommended. | | | | |
| Protective Gloves Impervious Gloves | Eye Protection Chemical Goggles or Face Mask | Other Protective Clothing Impermeable Apron or Protective Suit | | |
| Work/Hygiene Practices Always wash hands thoroughly after using chemical; never bring food, drink, or smoking materials into vicinity of chemicals. | | | | |

METHYL METHACRYLATE

CAS: 80-62-6

**IDENTIFICATION AND TYPICAL USES**

Methyl methacrylate is a clear, colorless liquid with an acrid, sweet, sharp, fruity odor. It is used as a monomer in the manufacture of polymethacrylate resins. It is also used in the impregnation of concrete, as a bone cement, as a dental ceramic filler or cement, as a medicinal spray adhesive or nonirritant bandage solvent, and also as a coating for contact lenses.

RISK ASSESSMENT: HEALTH**General Assessment**

Methyl methacrylate is a moderately toxic to humans by *inhalation* and mildly toxic by *ingestion* and skin contact (although dermal absorption has not been reported). It is a questioned animal carcinogen, but there are insufficient data regarding its carcinogenicity in humans. It is known to cause tumorigenic, teratogenic, and reproductive effects. Mutation data are also reported.

Inhalation results in irritation of the mucus membranes of the eyes, nose, throat, and respiratory system. There may be symptoms such as lethargy, coughing, wheezing, fatigue, cyanosis, and convulsive movements. High concentrations can cause dizziness with dyspnea, nausea, headache, vomiting, and can lead to sleep effects, excitement, anorexia, blood pressure decrease, and other symptoms of central nervous system depression.

Skin contact can cause serious localized irritation at the site of contact with inflammation, rash, and possible sensitization. Repeated exposures may cause parasthesia (tingling or pricking sensation on the skin). Eye contact is dangerous and there may be damage on contact with the liquid or vapor.

Ingestion of methyl methacrylate is not likely but is possible. It causes irritation of the mouth, lips, throat and gastrointestinal tract with painful swallowing, abdominal cramps, nausea, vomiting, and diarrhea.

☠ Acute Health Effects

The following acute (short-term) health effects may occur immediately or shortly after exposure to methyl methacrylate:

- Skin:** Serious localized irritation, erythema, rash, and sensitization.
- Eye:** Severe irritation which can lead to injury, burns, painful irritation, and permanent damage if allowed to remain in contact.
- Lung:** Irritation of the eyes, nose, throat and lungs (especially the mucus membranes). Will cause coughing, wheezing, congestion, and possible lung damage.
- CNS:** High concentrations may cause dizziness, headache, nausea, vomiting, dyspnea, lethargy, and convulsive movements.

☘ Chronic Health Effects

The following chronic (long-term) health effects may occur at some time after exposure to methyl methacrylate and can last for months or even years:

Cancer Hazards: According to the references, methyl methacrylate has been investigated for its ability to cause cancer in test animals and there is insufficient evidence to determine its carcinogenic effects. Its carcinogenicity is considered questioned in animals. Mutation data have been reported and many scientists believe that such chemicals may pose a cancer risk

Reproduction: According to the references, methyl methacrylate has shown to cause teratogenic effects in test animals as well as an ability to adversely affect the reproductive process.

Other Chronic Effects: Very high or prolonged exposure may lead to skin sensitization. Damage to the central nervous system can also occur in the long-term.

🔊 **Recommended Risk-Reduction Measures**

Because of its unknown but questioned carcinogenicity, as well as its known ability to cause teratogenic, mutagenic, and other systemic effects, personnel should avoid direct contact with methyl methacrylate. The best risk reduction measure is to use a less toxic chemical as a substitute for methyl methacrylate. If this is not possible or feasible, then *engineering controls* are the most effective method of reducing exposures. The best protection is to enclose operations and/or provide local exhaust ventilation at the site of chemical release. While not always operationally feasible, isolating operations can also reduce exposure risk.

Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around methyl methacrylate. For exposures exceeding the 100 ppm PEL (8-hour TWA), an organic vapor respirator may suffice. For higher concentrations, a supplied-air respirator with full facepiece operated in positive pressure mode, or a self-contained breathing apparatus (SCBA) with full facepiece and operated in pressure demand mode are the recommended respiratory protection methods of choice. If a full facepiece is not available, then chemical goggles should be worn to protect the eyes. Whenever a chemical splash hazard exists, a face shield and a protective apron should be worn. To prevent hand and skin exposures, impervious gloves should be used. Glove manufacturers should be contacted to obtain permeation studies before gloves are selected.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with methyl methacrylate.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard

Communication), prior to the first assignment in an area where methyl methacrylate is used or stored. Before beginning employment and at regular intervals thereafter (e.g., annually), those persons having frequent or potentially high exposures should be given the following medical tests:

- ☑ Lung function tests.
- ☑ Interview for brain effects, including recent memory problems, mood changes (irritability, withdrawal), difficulty with concentration, headaches, malaise, and altered sleep patterns. Cerebellar, autonomic, and peripheral nervous system evaluation is recommended. Positive or borderline cases should be referred for neuropsychological testing.

If symptoms develop or overexposure is suspected, the following medical tests are recommended:

- ☑ Examination of the nervous system.
- ☑ Lung function tests.
- ☑ Evaluation by a qualified allergist, including careful exposure history and special testing (may help diagnose skin allergy).

Any medical evaluation should include a careful history of past and present symptoms with an examination. Medical tests that look for existing damage are not a substitute for controlling exposures.

Other methods to reduce exposure include:

- ☑ Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not used, respiratory protection should be mandatory.
- ☑ Always ensure that proper protective clothing is worn when using chemical substances and that personnel are trained on its use and care.
- ☑ Wash thoroughly immediately after exposure to methyl methacrylate and at the end of the work shift or before eating, drinking, or smoking.
- ☑ Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of methyl methacrylate should be communicated to all exposed workers.
- ☑ Never eat, drink, or smoke in areas where methyl methacrylate is used, handled or stored.
- ☑ Work clothing contaminated with methyl methacrylate should never be worn home where family members can be exposed. It should be laun-

dered only by those who have been trained on the health risks associated with methyl methacrylate.

RISK ASSESSMENT: ENVIRONMENT

General Assessment

The environment is at risk of exposure during transportation, storage, disposal, or destruction of methyl methacrylate. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance. Accidental spills, large or small, can result in fire, explosion, and possible contamination of the surrounding environmental mediums (water, soil, and air).

Methyl methacrylate is considered a Class IB flammable liquid (according to OSHA 29 CFR 1910.106). Its low flash point and relatively low boiling point present a serious fire and explosion hazard concern. Also, because it is incompatible with a number of common materials, especially strong oxidizers, contact can result in violent and explosive reactions. It can also form explosive mixtures in air and can ignite on contact with heat, fire, or sparks. Heat can cause methyl methacrylate to react by itself. If this happens in a closed container, an explosion can occur. Methyl methacrylate usually contains an inhibitor such as hydroquinone or its methyl ether to prevent a self reaction. If the inhibitor is absent or present in too low a quantity, the explosive reaction may occur without the application of heat. These characteristics require special consideration during any emergency situation involving a leak or spill of methyl methacrylate.

Methyl methacrylate can enter the environment through unchecked industrial discharges and through spills.

☠ Acute Ecological Effects

Acute (short-term) toxic effects may include the death of animals, birds, or fish, and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to methyl methacrylate. This chemical has slight acute toxicity to aquatic life. Insufficient data are available to evaluate or predict the short-term effects of methyl methacrylate to plants, birds, or terrestrial animals.

☹ Chronic Ecological Effects

Chronic toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic

chemicals. Methyl methacrylate has slight chronic toxicity to aquatic life. Insufficient data are available to evaluate or predict the long-term effects of methyl methacrylate to plants, birds, or land animals.

💧 Water Solubility

Methyl methacrylate is moderately soluble in water. Concentrations of 1 to 1000 milligrams will mix with a liter of water.

⌚ Persistence in the Environment

Methyl methacrylate is slightly persistent in water, with a half-life of between 2 to 20 days. The half-life of a pollutant is the amount of time it takes for one-half of the chemical to be degraded. About 86% of methyl methacrylate will eventually end up in the air; the remainder will end up in the water.

🐟 Bioaccumulation in Aquatic Organisms

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans.

The concentration of methyl methacrylate found in fish tissues is expected to be about the same as the average concentration of methyl methacrylate in water from which the fish was taken.

🛡 Recommended Risk-Reduction Measures

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in a leak or spill to the environment. The correct use of DOT labeling (per the MSDS) on all containers, trucks, and rail cars will enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of methyl methacrylate should be segregated from incompatible chemicals to minimize the risk of cross-contamination or contact. Buildings designated for storage should be equipped with appropriate fire protection systems (alarms, sprinklers, emergency lighting, portable extinguishers). Equipment should be designed to meet explosion-proof standards.

If a spill or leak to the environment has occurred, fire department, emergency response, and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those

trained in proper spill containment procedures using non-sparking tools. Contaminated soils should be removed for incineration and replaced with clean soil. If methyl methacrylate should contact the water table, aquifer, or navigable waterway, time is of the essence. It is moderately soluble in water and, therefore, containment and remediation may not be entirely possible. When such spills occur, the local and/or state emergency response authorities must be notified. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of methyl methacrylate.

If methyl methacrylate is spilled or leaked, the following specific steps are recommended:

- Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened for normal work.
- Ventilate area of spill or leak.
- Remove all ignition sources.
- Absorb liquids in vermiculite, dry sand, earth, or a similar material and deposit in sealed containers for proper disposal. Use non-sparking tools during cleanup procedures.
- It may be necessary to dispose of methyl methacrylate as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving methyl methacrylate can present a moderate threat to business operations. The loss or damage of equipment or facilities can significantly affect fiscal viability. Lawsuits that may result from personnel injury/death, public exposures, and/or environmental contamination will also require a serious expenditure of resources.

Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business. Always remember that anytime the terms "cancer," "carcinogen," or "reproductive hazard" are used, public emotion, hysteria, and ignorance can run equally high. This should be carefully considered when developing or implementing a public relations policy.

Recommended Risk-Reduction Measures

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any procedures or policies intended to manage the use of chemicals in the workplace. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

SECTION I - GENERAL INFORMATION

| | | |
|--|--|---------------------------------|
| Characterization Polynuclear Aromatic | RCRA Number U165 | EPA Class Toxic Waste |
| DOT Proper Shipping Name Naphthalene | Chemical Abstract Service (CAS) Number 91-20-3 | |
| DOT Hazard Class and Label Requirements ORM-A; Flammable Solid | DOT Emergency Guide Code 32 | |
| DOT Identification Number UN 1334 (crude) UN2304 (molten) | Chemical Formula C₁₀H₈ | |

Synonyms

Naphthalin; tar camphor; white tar; mothballs.

SECTION II - HAZARDOUS INGREDIENTS AND IDENTITY INFORMATION

| Hazardous Components (specific identity) | OSHA Exposure Criteria | NIOSH Exposure Criteria | Immediately Dangerous to Life and Health (IDLH) | ACGIH Exposure Criteria |
|---|---|---|---|---|
| Naphthalene (derivation: From commercial anthracene and coal tar). 1 ppm = 5.33 mg/m³ | PEL: 10 ppm 50 mg/m³ STEL: 15 ppm 75 mg/m³ | REL: 10 ppm 50 mg/m³ STEL: 15 ppm 75 mg/m³ | 250 ppm | TLV: 10 ppm 50 mg/m³ STEL: 15 ppm 75 mg/m³ |

SECTION III - PHYSICAL AND CHEMICAL CHARACTERISTICS

| | |
|--|--|
| Boiling Point 424°F (218°C) | Specific Gravity (H ₂ O = 1) 1.15 |
| Vapor Pressure (mm Hg) 0.08 at 69°F (20°C) | Molecular Weight 128.2 |
| Vapor Density (Air = 1) 4.4 | Melting Point 176°F (80°C) |

Solubility

Slightly soluble in water (0.003%); dissolves in most organic solvents.

Appearance and Odor

White or colorless to brownish-orange crystalline solid flakes with an odor of mothballs. It is often shipped as a molten solid. Odor Threshold = 0.084 ppm.

SECTION IV - FIRE AND EXPLOSION HAZARD DATA

| | |
|---|--|
| Flash Point (method used) 174°F (79°C) opened cup | Explosive Limits in Air % by Volume LEL: 0.9% UEL: 5.9% |
| NFPA Classification Combustible Solid | Autoignition Temperature 979°F (526°C) |

Extinguishing Media

Carbon dioxide, dry chemical, water, or alcohol foam. Foam and water may cause extensive foaming.

Special Fire Fighting Procedures

Wear full protective clothing and self-contained breathing apparatus (SCBA). Poisonous gases are produced in fire.

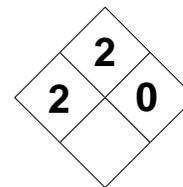

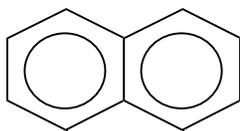

Unusual Fire and Explosion Hazards

Naphthalene is moderately explosive when exposed to flame. The vapors are much heavier than air and can collect in low areas or travel great distances to an ignition source and flashback to cause fire or explosion.

| SECTION V - REACTIVITY DATA | | | | |
|---|---|--|--|---|
| Stability | | Conditions to Avoid Naphthalene is normally stable under routine conditions of storage and handling. Avoid contact with heat and incompatible materials. | | |
| Stable X | Unstable | Incompatibility (<i>materials to avoid</i>) Incompatible with strong oxidizers (fluorine, bromine, chlorine), chromic anhydride, and mixtures of aluminum trichloride, and benzoyl chloride. | | |
| Hazardous Polymerization | | Conditions to Avoid Under normal conditions of temperature and pressure, hazardous polymerization of naphthalene is not expected to occur. | | |
| May Occur | Will Not Occur X | Hazardous Decomposition or By-products When heated to decomposition, naphthalene can emit carbon monoxide and acrid, irritating smoke. | | |
| SECTION VI - HEALTH HAZARD DATA | | | | |
| Primary Route(s) of Entry: | Inhalation? X | Absorption (skin/eye)? X | Ingestion? X | |
| Health Hazards INHALATION: Irritation of the respiratory tract, headache, nausea, vomiting, loss of appetite, slowed reactions, excitement, confusion, and other central nervous system effects. There is also risk of renal failure, blood disorders, jaundice, and eye damage. ABSORPTION: Coal tar derivatives may absorb through unbroken skin. Irritation with burning, itching, and edema (fluid buildup). Irritates the conjunctiva of the eye. INGESTION: Gastrointestinal tract irritation. | | | | |
| Carcinogenicity Unknown Human Questioned Animal | NTP Listed? No | IARC Cancer Review Group? No | OSHA Regulated? 29 CFR 1910.1000 Table Z-1 | Target Organs? Eyes, skin, blood, liver, kidneys, CNS |
| Medical Conditions Generally Aggravated by Exposure Diseases of the blood, liver, and kidneys may be aggravated upon exposure to naphthalene. | | | | |
| Emergency and First-aid Procedures <u>Eye contact:</u> Do not allow victim to keep eyes tightly shut. Flush immediately with water for 15 minutes (minimum); seek medical attention. <u>Skin contact:</u> Remove all contaminated clothing. Immediately wash area with large amounts of soap and water. For red or blistered skin, contact physician. For <u>inhalation:</u> Remove the person from exposure. Provide respiratory assistance and CPR. Transfer to medical facility. If <u>swallowed:</u> Seek medical attention immediately. Never give anything by mouth to an unconscious or convulsing person. | | | | |
| SECTION VII - PRECAUTIONS FOR SAFE HANDLING AND USE | | | | |
| Steps to be Taken in Case Material is Released or Spilled Collect powdered materials in most convenient and safe manner and deposit in sealed containers. Ventilate area of spill or leak. Remove all ignition sources. Restrict those not involved in cleanup from entering area. Notify appropriate authorities, as required by applicable environmental regulations. | | | | |
| Preferred Waste Disposal Method Incinerator equipped with scrubber and afterburner. | | | | |
| Precautions to be Taken in Handling and Storage Naphthalene is a combustible solid. Store to avoid contact with strong oxidizers, since violent reactions can occur. Store in tightly closed containers in cool, well-ventilated area away from heat. | | | | |
| Other Precautions and Warnings Sources of ignition (heat, flame, cigarettes, incompatibles) are prohibited where naphthalene is used, handled, or stored. Bulk storage of naphthalene is not recommended. | | | | |
| SECTION VIII - CONTROL MEASURES AND PERSONAL PROTECTIVE EQUIPMENT | | | | |
| Respiratory Protection (<i>specify type</i>) Use an MSHA/NIOSH-approved supplied-air respirator with full facepiece in continuous flow mode, or use a self-contained breathing apparatus (SCBA) with full facepiece operated in positive pressure mode. | | | | |
| Ventilation Local exhaust (preferred) at site of chemical work or general ventilation. | | | | |
| Protective Gloves Impervious Gloves | Eye Protection Chemical/Dust Goggles or Face Mask | Other Protective Clothing Boots; Aprons; Gauntlets | | |
| Work/Hygiene Practices Always wash hands thoroughly after using chemical; never bring food, drink, or smoking materials into vicinity of chemicals. | | | | |

NAPHTHALENEC₁₀H₈

CAS: 91-20-3

**IDENTIFICATION AND TYPICAL USES**

Naphthalene can appear as colorless or white to brownish-orange crystalline solid flakes with an odor of mothballs. It is normally shipped as a molten solid. It is used as an intermediate in the production of chlorinated naphthalenes, naphthyl, and naphthol derivatives, and dyes. It is also used as a moth repellent, a fungicide, a smokeless powder, a cutting fluid, a lubricant, in synthetic resins, for synthetic tanning, as a preservative, in textile chemicals, in emulsion breakers, in scintillation counters, and as an antiseptic.

RISK ASSESSMENT: HEALTH**General Assessment**

Naphthalene is a human poison by *ingestion*. It is also moderately toxic by *inhalation*. It is irritating to the skin and, on prolonged contact, can be *absorbed* through intact skin to cause toxic systemic effects. It is an experimental teratogen and has also caused adverse reproductive effects. Mutation data have been reported and naphthalene is also a questionable carcinogen in experimental tests.

Inhalation of naphthalene vapors causes central nervous system effects, including excitement, confusion, headache, nausea, and loss of appetite. Exposure by all routes of exposure may lead to renal shutdown (kidney failure), hemolytic effects (breakdown of the red blood cells), hematuria (blood in the urine), oliguria (decreased urine volume), jaundice, eye damage, and possible cataracts, vomiting, convulsions, and coma.

☠ Acute Health Effects

The following acute (short-term) health effects may occur immediately or shortly after exposure to naphthalene (within hours or days):

Skin: Irritation with burning, itching, and edema (buildup of fluid), redness and swelling.

Eye: Severe irritation of the conjunctiva with burning, itching, and watering. Direct contact with heated “fumes” can irritate the eyes.

Lung: Irritation of the bronchial tubes and other members of the respiratory tract. May cause headache, loss of appetite, nausea, vomiting, slowed reactions, and a loss of strength.

CNS: Depression of the nervous system causing excitement, convulsions, and possibly coma.

☛ Chronic Health Effects

The following chronic (long-term) health effects may occur at some time after exposure to naphthalene and can last for months or even years:

Cancer Hazards: Naphthalene may cause cancer in animals and mutations (genetic changes) in living cells. The data on its human carcinogenicity are inconclusive.

Reproductive Hazard: According to the references, naphthalene has been shown to cause teratogenic effects and adversely affect reproduction in test animals.

Other Chronic Effects: Continuous exposures to naphthalene may lead to an increased incidence of cataracts (opacities of the lens) and optical neuritis. There may be gastrointestinal effects, abdominal pain, irritated bladder, profuse sweating, and dermatitis.

🛡 Recommended Risk-Reduction Measures

Personnel should avoid direct contact with naphthalene. It is a questionable teratogen, mutagen, and carcinogen. If a less toxic chemical cannot be substituted for a hazardous substance, then *engineering controls* are the most effective method of reducing exposures. The best protection is to enclose operations and/or provide local exhaust ventilation at the site of chemical release. While not always operationally feasible, isolating operations can also reduce exposure. Using

respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around naphthalene. Air-purifying respirators will provide protection for exposures above the PEL. However, a self-contained breathing apparatus (SCBA) with full facepiece operated in pressure demand or a supplied-air respirator operated in continuous flow mode are the recommended respiratory protection methods of choice when working with a questioned carcinogen. If a full facepiece is not available, then chemical/dust goggles should be worn to protect the eyes. A face shield and a protective apron should also be worn. To prevent hand and skin exposures, impervious gloves should be used. Glove manufacturers should be contacted and permeation studies obtained *before* final glove selections have been made.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with naphthalene.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where naphthalene is used or stored.

Before beginning employment, and at regular intervals thereafter (e.g., annually), the following medical tests are recommended for personnel working with naphthalene:

- ☑ Anatomical examination of the eye and vision testing (establish a baseline).

If symptoms develop or overexposure is suspected, the following may be useful:

- ☑ Liver and kidney function tests.
- ☑ Complete blood count (CBC).
- ☑ Evaluation by a qualified allergist, including careful evaluation of exposure history and special testing (may help diagnose skin allergy).

Any evaluation should include a careful history of past and present symptoms with an examination. Medical tests that simply look for existing damage are not a substitute for controlling exposures.

Other methods to reduce exposure include:

- ☑ Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not used, respiratory protection should be mandatory.

- ☑ Always ensure that proper protective clothing is worn when using chemical substances.
- ☑ Wash thoroughly immediately after exposure to naphthalene and at the end of the work shift or before eating, drinking, or smoking. Avoid contact with direct sunlight.
- ☑ Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of naphthalene should be communicated to all exposed workers.
- ☑ Eye wash stations should be provided in the immediate work area for emergency use. If there is a possibility of skin exposure to naphthalene, emergency shower facilities should also be provided.

RISK ASSESSMENT: ENVIRONMENT

General Assessment

The environment is at risk of exposure during transportation, storage, disposal, or destruction of naphthalene. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance. Accidental spills, large or small, can result in fire, explosion (depending upon conditions of spill), and possible contamination of the surrounding environmental mediums (water, soil, and air).

Naphthalene is considered a combustible solid. Alone, its high flash point and autoignition temperature do not present a serious fire or explosion hazard. However, because it is incompatible with many other commodities, extreme caution is required in handling, storage, transportation, and disposal of naphthalene. These characteristics also require special consideration during any emergency situation involving a leak or spill of naphthalene crystals. Even as a solid, it has a considerably high vapor pressure. Vapors are heavier than air and can collect in low lying areas. Should naphthalene ever come into contact with incompatible substances (such as oxidizers) either during use, transportation, storage, or disposal, the formation of highly toxic and/or highly explosive commodities is extremely possible.

The proper disposal/destruction method for naphthalene waste is to burn it in a chemical incinerator equipped with an afterburner and air scrubber.

Naphthalene can enter the environment from industrial and municipal plant discharges and from spills.

☠ *Acute Ecological Effects*

Acute (short-term) toxic effects may include the death of animals, birds, or fish and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to naphthalene.

This chemical has moderate acute toxicity to aquatic life and has caused injury or death to various types of agricultural and ornamental crops. Insufficient data are available to evaluate or predict the short-term effects of naphthalene to birds or land animals.

🌱 *Chronic Ecological Effects*

Chronic (long-term) toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals.

Naphthalene has moderate chronic toxicity to aquatic life. Insufficient data are available to evaluate or predict the long-term effects of naphthalene to plants, birds, or land animals.

💧 *Water Solubility*

Naphthalene is very slightly soluble in water. Concentrations of 1 milligram or less will mix with a liter of water.

🕒 *Persistence in the Environment*

Naphthalene is slightly persistent in water, with a half-life between 2 and 20 days. The half-life of a pollutant is the amount of time it takes for one half of the chemical to be degraded. Approximately 96% of naphthalene will eventually end up in air; about 3% will end up in water; and about 0.5% will end up in both aquatic sediments and terrestrial soils, respectively.

🐟 *Bioaccumulation in Aquatic Organisms*

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans.

The concentration of naphthalene found in fish tissues is expected to be somewhat higher than the average concentration of naphthalene in the water from which the fish was taken.

🛑 *Recommended Risk-Reduction Measures*

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in a leak or spill of naphthalene into the environment. The correct use of DOT labeling (per the MSDS) on all containers, trucks, and rail cars will enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of naphthalene should be segregated from incompatible chemicals to minimize the risk of cross-contamination or contact. Personnel working in storage areas must be trained on the hazards of naphthalene.

If a spill or leak to the environment has occurred, fire department, emergency response and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those trained in proper spill containment procedures. Contaminated soils should be removed for incineration and replaced with clean soil. If naphthalene should contact the water table, aquifer, or navigable waterway, the local and/or state emergency response authorities must be notified. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of naphthalene. If naphthalene is spilled or leaked, the following specific steps are recommended:

- ☑ Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened for normal work.
- ☑ Remove all ignition sources.
- ☑ Collect powdered materials in the safest manner possible and deposit in sealed containers. Do NOT dry sweep. Use vacuum equipped with a HEPA filter instead. Damp mop residue.
- ☑ It may be necessary to dispose of naphthalene as a hazardous waste. The responsible state agency or the regional office of the federal Environmental Protection Agency (EPA) should be contacted for specific recommendations.

RISK ASSESSMENT: BUSINESS

General Assessment

Accidents or mishaps involving naphthalene can present a significant threat to business operations. The loss or damage of equipment or facilities can significantly affect fiscal viability. Lawsuits that may result from personnel injury/death, public exposures, and/or

Risk Management for Hazardous Chemicals

environmental contamination will also require a serious expenditure of resources.

Media attention surrounding an injury, death, or environmental damage can also result in a loss of profits and loss of current as well as future business. Always remember that anytime the terms "cancer," "carcinogen," or "reproductive hazard" are used, public emotion, hysteria, and ignorance can run equally high. This should be carefully considered when drafting or implementing public relations policies.

🕒 Recommended Risk-Reduction Measures

Company attorneys, safety and health professionals, and environmental specialists should be involved in the development of any safety, health or environmental policies or procedures. A company official should be pre-designated as a public relations officer with specific training in dealing with the press. Corporate plans and policies should be developed, approved, and implemented long before any need for such arises.

Use HEPA vacuum and deposit in sealed drums. | | | | |
| Preferred Waste Disposal Method Consider reclamation or recycling, if possible. | | | | |
| Precautions to be Taken in Handling and Storage Store in tightly closed containers in cool, well-ventilated location away from heat. Protect containers from physical damage. A regulated controlled area must be established per OSHA 29 CFR 1910.1004. | | | | |
| Other Precautions and Warnings Sources of ignition (open flame or smoking), are prohibited where 1-naphthylamine is used or stored. Metal containers should be used. Do NOT generate dust clouds or dusty conditions when working. | | | | |
| SECTION VIII - CONTROL MEASURES AND PERSONAL PROTECTIVE EQUIPMENT | | | | |
| Respiratory Protection (<i>specify type</i>) Use a NIOSH-approved powered air-purifying respirator or a self-contained breathing apparatus (SCBA) with full facepiece operated in positive pressure mode. | | | | |
| Ventilation Local exhaust (preferred) at site of chemical work or general ventilation. | | | | |
| Protective Gloves Impervious Gloves | Eye Protection Chemical/Dust Goggles or Face Mask | Other Protective Clothing Protective Clothing (prevent skin contact) | | |
| Work/Hygiene Practices Always wash hands thoroughly after using chemical; never bring food, drink, or smoking materials into vicinity of chemicals. | | | | |

1-NAPHTHYLAMINEC₁₀H₇NH₂

CAS: 134-32-7

**IDENTIFICATION AND TYPICAL USES**

1-Naphthylamine is a colorless crystalline solid with an unpleasant, ammonia-like odor. It will darken to reddish-purple when exposed to air. It is used in the manufacture of dyes, intermediates, and tonic prints. It is also used in agricultural chemicals.

RISK ASSESSMENT: HEALTH
General Assessment

1-Naphthylamine is a human poison by *inhalation*, *ingestion*, and *absorption* through intact skin. It has been suggested that exposure to this chemical may lead to bladder cancer. Mutation data have also been reported. Its human teratogenicity and reproductive health risks are unknown. 1-Naphthylamine is soluble in fats and lipids.

Inhalation of the dusts, as well as skin absorption, causes irritation of the skin, eyes, nose, throat, and the mucous membranes lining the respiratory tract. There can be eczema, tachycardia (rapid heartbeat) hypertension (increased blood pressure) cough, sneezing, headache, fatigue, anorexia, painful diarrhea, loss of appetite with subsequent weight loss, low body temperature, cyanosis (blue discoloration of the skin, especially on face, hands, and feet due to oxygen deficiency), vomiting, and emaciation. There can also be serious bladder disorders, including hematuria (blood in urine) and proteinuria (excessive proteins in urine), as well as bladder damage (including cancer).

Ingestion can lead to symptoms of inhalation and absorption, as well as acute hemorrhagic cystitis, dyspnea, ataxia, and dysuria (infrequent urination).

☠ Acute Health Effects

The following acute (short-term) health effects may occur immediately or shortly after exposure to 1-naphthylamine:

Skin: Irritation with rash and localized inflammation. Absorption through intact skin is likely on short exposures.

Eye: Severe irritation, pain, and inflammation.

Lung: Nose, throat, and respiratory tract irritation causing coughing, sneezing, and toxic systemic effects.

Other: Ingestion may cause hemorrhagic cystitis.

☠* Chronic Health Effects

The following chronic (long-term) health effects may occur at some time after exposure to 1-naphthylamine and can last for months or even years:

Cancer Hazards: According to the information presented in the references, 1-naphthylamine is suspected to cause cancer of the bladder. Mutation data have also been recorded and many scientists believe that such chemicals pose a cancer risk in the long-term.

Reproductive Hazard: According to information presented in the references, 1-naphthylamine has not been adequately tested for its ability to cause cancer in test animals.

🛡 Recommended Risk-Reduction Measures

Personnel should avoid direct contact with 1-naphthylamine. It is suspected to cause cancer of the bladder. Occupational poisoning occurs most commonly by all routes of exposure. Substitution with a

non-cancer agent is recommended. However, if a less toxic material or compound cannot be substituted for 1-naphthylamine, then *engineering controls* are the most effective method of reducing exposures. The best protection is to enclose operations and/or provide local exhaust ventilation at the site of 1-naphthylamine release. While not always operationally feasible, isolating operations can also reduce exposure. Using respiratory protection is less effective than the controls mentioned above, but is still advisable whenever working with or around 1-naphthylamine. For the best protection, use an MSHA/NIOSH-approved self-contained breathing apparatus (SCBA) with full facepiece operated in pressure demand or a supplied-air respirator operated in continuous flow, especially when high exposures to 1-naphthylamine are anticipated. If a full facepiece is not available, then chemical/dust goggles should be worn to protect the eyes. A face shield should also be considered. To prevent hand and skin exposures, impervious gloves should be used. Glove manufacturers should be contacted and permeation studies obtained *before* glove selections are made.

Administrative controls should also be in place to minimize the potential for human exposures. These may include written procedures or policies which specify the methods and techniques that will be practiced whenever personnel are to work with 1-naphthylamine.

All personnel should receive *training* on the use, hazards, protective measures, emergency actions, and other precautions per 29 CFR 1910.1200 (Hazard Communication), prior to the first assignment in an area where 1-naphthylamine is used or stored.

Before beginning employment and at regular times thereafter, the following recommended medical tests should be considered:

- ☑ Complete blood count (CBC).
- ☑ Urinalysis to test for blood and protein levels in urine (establish baseline).

If symptoms should develop or overexposure is suspected, the following additional tests may be helpful:

- ☑ Complete blood count.
- ☑ Urinalysis (compare to baseline).

Any evaluation should include a careful history of past and present symptoms with an examination. Medical tests that simply look for existing damage are not a substitute for controlling exposures.

Other methods to reduce exposure include:

- ☑ Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not used, respiratory protection should be mandatory.
- ☑ Always ensure that proper protective clothing is worn when using chemical substances and that personnel are trained on its use and care.
- ☑ Wash thoroughly immediately after exposure to 1-naphthylamine and at the end of the work shift or before eating, drinking, or smoking.
- ☑ A regulated, marked controlled area must be established wherever 1-naphthylamine is used, handled or stored. Other requirements are established by OSHA (29 CFR 1910.1004).
- ☑ Hazard warning information should be posted in the work area. In addition, as part of an on-going education and training program, all information on the health and safety hazards of 1-naphthylamine should be communicated to all potentially exposed workers.
- ☑ Eye wash stations should be provided in the immediate work area for emergency use. If there is a possibility of skin exposure to 1-naphthylamine, emergency shower facilities should be provided.
- ☑ Workers whose clothing has been contaminated by 1-naphthylamine should change into clean clothes before leaving work. Contaminated work clothing should be laundered only by individuals who have been informed of the hazards of exposure to 1-naphthylamine.

RISK ASSESSMENT: ENVIRONMENT

General Assessment

The environment is at risk of exposure during transportation, storage, disposal, or destruction of 1-naphthylamine. In almost every scenario, the threat of environmental exposure is contingent upon the proper handling of the chemical substance. Accidental spills, large or small, can result in contamination of the surrounding environmental mediums (water, soil, and air).

1-Naphthylamine is a combustible solid. It can present a dangerous explosion hazard if its dusts form a cloud and come into contact with an ignition source. It is also incompatible with oxidizing materials and contact can result in violent and explosive reactions. Caution is always required in handling, storage, trans-

portation, and disposal of 1-naphthylamine. Emergency responders should be made aware of the presence of 1-naphthylamine at any emergency response situation.

1-Naphthylamine can enter the environment from industrial effluents and from spills.

☠ *Acute Ecological Effects*

Acute (short-term) toxic effects may include the death of animals, birds, or fish and death or low growth rate in plants. Acute effects are seen 2 to 4 days after animals or plants are exposed to 1-naphthylamine.

Insufficient data are available to evaluate or predict the short-term effects of 1-naphthylamine to aquatic life, plants, birds, or terrestrial animals.

🕒 *Chronic Ecological Effects*

Chronic (long-term) toxic effects may include shortened life span, reproductive problems, lower fertility, and changes in appearance or behavior in exposed animals. These effects can be seen long after first exposure(s) to toxic chemicals.

Insufficient data are available to evaluate or predict the long-term effects of 1-naphthylamine to aquatic life, plants, birds, or terrestrial animals.

💧 *Water Solubility*

1-Naphthylamine is nearly insoluble in water. Concentrations of less than 1 milligram will mix with a liter of water.

🕒 *Persistence in the Environment*

1-Naphthylamine is highly persistent in water, with a half-life of greater than 200 days. The half-life of a pollutant is the amount of time it takes for one half of the chemical to be degraded.

🐟 *Bioaccumulation in Aquatic Organisms*

Some substances increase in concentration, or *bioaccumulate*, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals as well as humans.

The concentration of 1-naphthylamine found in fish tissues is expected to be somewhat higher than the average concentration of 1-naphthylamine in the water from which the fish was taken.

🛡️ *Recommended Risk-Reduction Measures*

Proper training of all transporters will reduce the likelihood of a mishap or accident resulting in a leak or spill of 1-naphthylamine into the environment. Labels on all containers, trucks, and rail cars must meet DOT requirements and accurately reflect their contents to enable emergency responders to react properly and quickly to any disaster thereby reducing the potential risk to the environment and to personnel.

Storage of 1-naphthylamine should be segregated from other chemicals and materials to minimize the risk of cross-contamination.

If a spill or leak to the environment has occurred, fire department, emergency response and/or hazardous materials spill personnel should be notified immediately. Cleanup should be attempted only by those trained in proper spill containment procedures. Contaminated soils should be removed for incineration and replaced with clean soil. If 1-naphthylamine should contact the water table, aquifer, or navigable waterway, time is of the essence. It is practically insoluble and total containment and remediation may be possible. The local and/or state emergency response authorities must be notified. A comprehensive emergency response or disaster preparedness/recovery plan should be in place prior to any operations involving the use, transportation, storage, or disposal of 1-naphthylamine.

If 1-naphthylamine is spilled or leaked, the following specific steps are recommended:

- ☑ Restrict persons not wearing protective clothing from area of spill or leak until cleanup is complete and area can be opened for normal work.
